The Semitic languages are part of the Afroasiatic family. In the ancient world, Semitic languages were spoken from the western Mediterranean in the west to Iraq in the east, and from Ethiopia north to Anatolia. Many Semitic languages are still spoken today. Arabic is by far the most common; some dialect of Arabic is spoken by some 200 million speakers, from Morocco to Tajikistan, and it is also used, in its Classical and Modern Standard forms, for religious and other formal purposes. Modern Standard Arabic is the official or national language of countries throughout the Middle East and northern and northeastern Africa, and Classical Arabic has been and still is used for religious purposes all over the world, following the spread of Islam. Modern Ethiopic languages like Amharic, Tigrinya, and Tigre are spoken by 25 million people in Ethiopia and Eritrea. Modern Hebrew is the language of 5 million inhabitants of Israel. In Yemen and Oman, Modern South Arabian languages like Mehri, Jibbali, and Soqotri have around 60 000 speakers. And Aramaic dialects continue as the languages of a few hundred thousand speakers who have left the Middle East in recent years and spread far and wide.

Our earliest attestations of a Semitic language occur in Sumerian texts of the first half of the 3rd millennium. Sumerian is not a Semitic language, but within these early texts we can recognize Akkadian names and Akkadian loanwords into Sumerian. By around 2500 B.C., entire texts written in Akkadian start to appear.

Proto-Semitic is a scholarly reconstruction that suggests a common source to which all the known languages of the Semitic language family can be traced. Although the Semitic languages are thought to descend from some common ancestor, Proto-Semitic is not that ancestor; the term is not meant to represent a language that was ever spoken. It is instead the most economical reconstruction from which the known languages could have developed, through well-established phonological, morphological, and syntactical rules. We postulate a tense-mood-aspect verbal system with a perfective conjugation (**yaqtul*) and an imperfective conjugation (**yaqattal*). There was also a verbal adjective (**qatil* + enclitic pronouns). Another characteristic of the Semitic verbal system is a set of derived verbal stems, derived from the basic stem (the G, for *Grundstamm*), including one that doubles the middle root consonant (the D stem), a causative stem with some sort of causative affix (the C stem), a passive stem with infixed or prefixed *-n-* (the N stem), a medio-passive stem with infixed or prefixed *-t-* (the various t-stems), and

Introduction

The Semitic languages are part of the Afroasiatic family. In the ancient world, Semitic languages were spoken from the western Mediterranean in the west to Iraq in the east, and from Ethiopia north to Anatolia. Many Semitic languages are still spoken today. Arabic is by far the most common; some dialect of Arabic is spoken by some 200 million speakers, from Morocco to Tajikistan, and it is also used, in its Classical and Modern Standard forms, for religious and other formal purposes. Modern Standard Arabic is the official or national language of countries throughout the Middle East and northern and northeastern Africa, and Classical Arabic has been and still is used for religious purposes all over the world, following the spread of Islam. Modern Ethiopic languages like Amharic, Tigrinya, and Tigre are spoken by 25 million people in Ethiopia and Eritrea. Modern Hebrew is the language of 5 million inhabitants of Israel. In Yemen and Oman, Modern South Arabian languages like Mehri, Jibbali, and Soqotri have around 60 000 speakers. And Aramaic dialects continue as the languages of a few hundred thousand speakers who have left the Middle East in recent years and spread far and wide.

Our earliest attestations of a Semitic language occur in Sumerian texts of the first half of the 3rd millennium. Sumerian is not a Semitic language, but within these early texts we can recognize Akkadian names and Akkadian loanwords into Sumerian. By around 2500 B.C., entire texts written in Akkadian start to appear.

Proto-Semitic is a scholarly reconstruction that suggests a common source to which all the known languages of the Semitic language family can be traced. Although the Semitic languages are thought to descend from some common ancestor, Proto-Semitic is not that ancestor; the term is not meant to represent a language that was ever spoken. It is instead the most economical reconstruction from which the known languages could have developed, through well-established phonological, morphological, and syntactical rules. We postulate a tense-mood-aspect verbal system with a perfective conjugation (**yaqtul*) and an imperfective conjugation (**yaqattal*). There was also a verbal adjective (**qatil* + enclitic pronouns). Another characteristic of the Semitic verbal system is a set of derived verbal stems, derived from the basic stem (the G, for *Grundstamm*), including one that doubles the middle root consonant (the D stem), a causative stem with some sort of causative affix (the C stem), a passive stem with infixed or prefixed *-n-* (the N stem), a medio-passive stem with infixed or prefixed *-t-* (the various t-stems), and

possibly others. Nominals in Semitic have case endings (nominative, genitive, accusative in the singular; nominative and oblique in the plural), two genders, and three numbers (singular, dual, plural), plus both bound and unbound states of a noun.

These languages typically form words around triconsonantal 'roots.' Although there are words that cannot be related to a verbal root at all, and others that appear to have developed from fewer than three consonants, the vast majority of lexical items are formed by patterns of vowels and affixes interdigitated into and around the three consonants that carry the meaning of a given root. Thirty consonant phonemes are reconstructed for Proto-Semitic: bilabials p, b, m, and w; interdentals θ, θ', and ð; dental/alveolars t, t', d, ^{t}s, ^{t}s', ^{d}z, s, ɬ, ɬ', l, r, and n; palatal y; velars k, k', g, x, x̣, and ɣ; pharyngeal ħ and '; and glottal ' and h. We reconstruct three short and three long vowels: a, i, u, ā, ī, ū.

Verbal sentences in Semitic are typically V-S-O, and adjectives follow the nouns they modify. There is a genitive chain, called a construct chain, that consists of two or more nouns, the first of which can be in any case, but the remaining members are genitive. For the most part, this chain describes the 'of' relation: for instance, 'the king of the land' would be 'king' + case ending followed by 'the land' + genitive case ending. Adjectives and the nouns they modify must agree in gender and number, except that the numerals from three to ten have the odd feature that the feminine-looking numeral modifies the masculine noun, and the masculine-looking numeral modifies the feminine noun. Some of these features can be followed through the innovations that define the various branches of Semitic.

East and West Semitic

The Semitic languages are a fairly close-knit family. Semitic divides into two major groupings, East Semitic and West Semitic.

East Semitic

East Semitic is made up of Akkadian and Eblaite.

Akkadian Akkadian is the language of ancient Mesopotamia (ancient Iraq), and so far hundreds of thousands of Akkadian texts have come to light. It is written in left-to-right cuneiform, inscribed with a stylus on clay tablets. Akkadian cuneiform uses logograms and syllabic signs, with vC, Cv, and CvC syllables. Akkadian can be broken down into several dialects. In the 3rd millennium, we use the term Old Akkadian for a number of dialects used to write royal inscriptions, letters, ritual texts, administrative texts, and literary texts. Beginning in the early 2nd millennium, the umbrella term Akkadian is replaced by Assyrian and Babylonian. Old Assyrian is the language of some 15 000 early 2nd-millennium documents, mostly written by or for merchants residing in Anatolia. The name Old Babylonian covers the many thousands of texts from the first half of the 2nd millennium, especially from the First Dynasty of Babylon, of which Hammurabi is the most famous king. These texts are letters, omen texts, literary texts, administrative texts, and laws, including the famous law code of Hammurabi.

Both Middle Assyrian and Middle Babylonian, from the second half of the 2nd millennium, are less fully documented, but with the same array of genres. For much of the 2nd millennium, Akkadian was a lingua franca for the entire Near East, and Peripheral Akkadian texts are found from Egypt (especially the el-Amarna archive of letters from Palestinian governors) to Syria (especially the administrative texts from ancient Ugarit, modern Ras Shamra) to Anatolia (the archive from ancient Hattusa, modern Boghazköy).

Neo-Babylonian texts survive from the first half of the 1st millennium, largely letters and administrative texts, and Late Babylonian continues in use until the 1st century A.D. Neo-Assyrian, the language of the Neo-Assyrian Empire, stretches from the early 1st millennium until the fall of the empire in the late 7th century B.C. These documents are far more numerous than the Babylonian texts of the 1st millennium. Finally, Standard Babylonian refers to the archaizing written language in use in the first half of the 1st millennium, in which both Babylonians and Assyrians recorded religious and literary texts, royal inscriptions, and other formal texts.

Eblaite A cache of texts was uncovered beginning in the 1970s at Tell Mardikh in Syria, the ancient city of Ebla. These texts, which date to the 24th or 23rd century B.C., are largely in Sumerian, but bilingual lexical lists and some other texts display another language that is not Sumerian and not Akkadian, but seems to be closely related to Akkadian. It is this language that is dubbed Eblaite.

West Semitic

The West Semitic languages are separated from the East Semitic by an innovation that can be seen in all West Semitic languages: the development of an original verbal adjective **qatil* + case ending into an active, perfective suffix conjugation, **qatala*. This new perfective conjugation replaces the Common Semitic

perfective/volitive form **yaqtul*, which continued in use in West Semitic, especially as a volitive, but as a past tense form only in restricted environments. West Semitic itself can be divided into the Ethiopian languages, the Modern South Arabian languages, and the Central Semitic languages.

Ethiopian Classical Ethiopic (Geʿez) is attested beginning in the 4th century A.D. as the language of ancient Aksum and probably went out of use as a spoken language in the 10th century, with the demise of the Aksumite Empire. It continued, however, as the language of the Ethiopian church and as a general literary language until recently. Closely related to Geʿez are the Northern Ethiopian languages Tigrinya and Tigre, spoken in Eritrea. Amharic, the official language of Ethiopia, is the best known of the Southern Ethiopian languages. It is generally thought that the Ethiopian languages came to east Africa from the southwest Arabian peninsula, probably no earlier than the 1st millennium B.C. The earliest Geʿez was written in the alphabet used for Old South Arabian inscriptions; this alphabet later developed into a distinctive Ethiopic syllabary with the addition of vowel marks.

Ethiopian languages use the innovated **qatala* perfective form, but are differentiated from the Central Semitic by their retention of the old Common Semitic imperfective form **yaqattal*, with doubled middle radical, which they share with East Semitic.

Modern South Arabian The Modern South Arabian languages (particularly Mehri, but also Jibbali, Hobyót, Harsusi, Soqotri, and several smaller groups), are spoken by around 60 000 people (and dwindling) in Yemen and Oman. They have only recently been written down and so have no literary history; there is also no script associated with them, since we know them from transcriptions into the Latin or Arabic alphabet. Like the Ethiopian languages, Modern South Arabian languages have both the innovated **qatala* perfective and the retained **yaqattal* imperfective. These languages are not the descendants of the Epigraphic or Old South Arabian inscriptions (see below).

Central Semitic The Central Semitic languages break off from the rest of West Semitic with the innovation of a new imperfective form **yaqtulu*, probably a development from an old subjunctive form such as we see in Akkadian **yaqtul-u* used in subordinate clauses. The Central Semitic languages also exhibit the innovated **qatala* perfective that defines all West Semitic languages. Volitive **yaqtul* remains but can be confused with imperfective **yaqtulu* in languages without final short vowels; preterite **yaqtul* is also used in certain restricted environments such as the *waw*-consecutive preterite *wayyiqtol* forms in Classical Hebrew. The Central Semitic branch is divided into Old South Arabian, North Arabian, and Syro-Palestinian or Northwest Semitic.

Old South Arabian The Old South Arabian (or Ancient South Arabian) inscriptions (or Sayhadic) date from the 8th century B.C. to the 6th century A.D. This umbrella term includes several dialects, the best attested of which is Sabaean (or Sabaic); inscriptions are also found in Hadramitic, Minaean, and Qatabanian dialects, but in much smaller numbers. There are at present more than 10 000 stone inscriptions in Sabaean, and a recent find of many inscriptions on short wooden sticks in a cursive script, probably from the 2nd or 3rd century A.D., has greatly increased our knowledge of the grammar of this language.

Recent work has shown that the language of the Old South Arabian inscriptions should be classified along with Central Semitic rather than the traditional South Semitic classification. I-*w* verbs in these inscriptions never have *w* in the prefix conjugation, and since the **yaqattal* form would show the *w*, the prefix conjugation must be not **yaqattal*, but rather the Central Semitic **yaqtul*.

The earliest Sabaean inscriptions are mainly written boustrophedon; otherwise, writing is from right to left. The majority of the stone inscriptions fall into the following categories: graffiti, mostly personal names; dedicatory inscriptions; building inscriptions; reports of military campaigns; legal documents; funerary inscriptions. The inscriptions on wood at least partly concern legal and economic matters, sometimes written in the form of a letter.

The South Semitic alphabet, which broke off from the early Canaanite linear alphabet around the 13th century B.C., represented only consonants. The Old South Arabian inscriptions maintain this system of writing, with rare indications of vowels.

North Arabian The North Arabian languages of the Central Semitic branch are divided into two groups: Arabic, including Old Arabic, Classical, and modern dialects; and Old North Arabian (or Ancient North Arabian).

Old North Arabian includes inscriptions in pre-Islamic dialects, dating from the 8th century B.C. to the 4th century A.D.: Oasis North Arabian (Taymanite, Dedanite, Dumaitic, and Dispersed Oasis North Arabian); Safaitic; Thamudic; and Hismaic; plus what is generally called Hasaitic – a dialect seen in a few dozen mostly funerary inscriptions from

northeastern Arabia, near the Persian Gulf, probably dating from the second half of the 1st millennium B.C. Old North Arabian inscriptions are largely graffiti, and so the handwriting is mostly informal, not highly trained; therefore, the dating and even ancestor of some of the individual scripts are not clear. For the most part, however, Old North Arabian inscriptions are written in a script closely related to that of the Old South Arabian inscriptions. The number of graffiti and their dispersal patterns are astounding in their implications for literacy, both in the towns and among the nomads, since thousands of the graffiti so far published were written on rocks in the desert areas that stretch from Syria to northern Arabia. The writing of the Oasis texts was usually right to left, and sometimes boustrophedon, while the nomads' writing on rocks goes in every possible direction, including a spiral, across the surface of the rocks on which they were written.

The Oasis dialects are those used in the oases associated with the routes of the spice and aromatics trade (especially frankincense). Approximately 400 short inscriptions found in and around the oasis of Tayma have been published so far, in a dialect and script that are somewhat different from the rest of Old North Arabian. They probably date to the 6th or 5th century B.C. Two inscriptions have recently been published that mention "Nabonidus, king of Babylon"; Nabonidus in fact spent ten years of his reign in Tayma in the mid-6th century B.C. Dedanite is the dialect of hundreds of graffiti found in the vicinity of the oasis of Dedan. It is the only one of these dialects used for monumental inscriptions as well, and so far hundreds of mostly dedicatory monumental inscriptions have been found. Dedanite inscriptions probably date to the second half of the 1st millennium B.C. The Dumaitic dialect is represented by only three texts so far, found in or near Sakaka in northern Arabia. There is very little evidence for dating, but they may also be from the second half of the 1st millennium B.C. The Dispersed Oasis North Arabian are those texts that are clearly related to the Oasis North Arabian but are found outside Arabia, carried north by traders and found mostly in what was Mesopotamia.

Of the Safaitic, Thamudic, and Hismaic inscriptions, the Safaitic are the most numerous, with some 15 000 graffiti from the 1st century B.C. to the 4th century A.D.; written by nomads, they are found as far north as Damascus and east to the Euphrates, as well as south to northern Arabia. Hismaic inscriptions are written in the language of the Hisma desert nomads, and they stretch from northwestern Arabia to central and northern Jordan. Approximately 1000 Thamudic graffiti date from the 6th century B.C. to the 3rd century A.D. Thamudic includes all the non-Oasis Old North Arabian inscriptions that are not otherwise classified.

The prominent difference between Old North Arabian and Arabic is the definite article in each: *'al-* in Arabic, but *h-* in Old North Arabian.

Classical Arabic has made its way around the world as the literary language of Islam, but a dialect or dialects similar to Classical Arabic were known already in 4th-century A.D. inscriptions (hence the name Old Arabic). Classical Arabic has elements of spoken pre-Islamic Arabic, but was shaped by the Qur'an (7th century A.D.), which reflects also the spoken dialect of the Hejaz region of central and west Arabia, in particular, the dialect of Mecca which was Muhammad's dialect. Arabic script was adapted from the script of the Nabateans. It is written from right to left and was originally consonantal, with indication of long vowels, and has developed diacritical marks to indicate short vowels and other features. The 8th- and 9th-century Arab grammarians standardized the language, and it has changed very little since that time.

Modern Standard Arabic, which is the Arabic of newspapers, radio, television, and international communication, is still Classical Arabic at its base, with vocabulary updated as necessary. A development from Classical Arabic is Middle Arabic, which is meant to be literary Arabic, but deviates from it in ways that betray the authors' dialects; examples of Middle Arabic are Judeo-Arabic, Medieval Christian Arabic, and Spanish Arabic. Finally, there are the modern vernacular dialects of Arabic that have evolved over the centuries over the large territory in which Arabic is spoken. Many, in fact, are no longer mutually comprehensible, especially at the outer ends of that territory, so that someone speaking in the vernacular dialect of Morocco and someone speaking in the vernacular dialect of Iraq would have to move closer and closer to the classical language until they came to a point where each could comfortably understand the other. Arabic is one of the most commonly spoken languages in the world, with approximately 200 million speakers.

Northwest Semitic The Northwest Semitic (or Syro-Palestinian) languages can be divided into at least four subcategories: Ugaritic, Canaanite, Aramaic, and other. These languages all share the innovations of West and Central Semitic, plus two more: the change of initial **w* to **y* in virtually all environments except for the word 'and,' which remains proclitic **wa-*; and the plural pattern that adds *-a-* insertion to the regular external plural, for nouns of the type $C_1vC_2C_3$. Thus, **sipr-* 'book'; plural **siparūma/siparīma* (Hebrew *sḗper, səpārîm*).

Ugaritic is the language attested from the late 14th century to around 1200 B.C. at the ancient city of Ugarit (modern Ras Shamra) on the Syrian coast above Latakia, and at an outlying town called Ras Ibn Hani. It is known from the approximately 1500 texts written left to right in alphabetic cuneiform on clay tablets. The writing system postdates the linear alphabet known from the same general region and seems to be a clever combination of the technology of cuneiform writing on clay (like the lingua franca at the time, Akkadian) and the idea of an alphabet and the ease of writing it affords. Ugaritic is written without vowels, but there are some multilingual texts with columns that represent the Ugaritic pronunciation written out in syllabic cuneiform, so that the vocalization of some words and some basic rules are known. Further, there are three signs for *'aleph,* representing, among other things, the consonant *'aleph* plus vowels a, i, and u, so words with *'aleph* as a root letter often have some indication of the vocalization of that word and by extension other words of the same type (perfective verb, for instance). The corpus consists of poetic mythological texts, ritual texts, administrative texts, letters, and school texts.

Ugaritic is sometimes thought to be a Canaanite language rather than a branch on its own, but there is at least one of the defining innovations of Canaanite that Ugaritic does not participate in (see below on 'intensive' and causative stems); perhaps there were more, but they cannot be seen in the Ugaritic consonantal alphabet, even with the aids mentioned above. Canaanite describes a grouping of closely related languages: early Canaanite seen in scattered inscriptions and in the underlying dialects of the Amarna letter scribes (see below); Phoenician; Moabite; Hebrew; Ammonite; and Edomite. These languages share a change of the 'intensive' and causative conjugation perfective verb forms from **qattila* and **haqtila* to **qittila* and **hiqtila*, and the so-called Canaanite shift of *ā* to *ō*, among others. While these languages are written consonantally, later vocalizations (of Biblical Hebrew, for instance) and the spelling out of words in contemporaneous Akkadian, Greek, and Roman documents allow us to reconstruct many of these changes where they are not obvious.

Ancient Canaan covered roughly modern southern Lebanon, Israel, and the northwestern part of Jordan. The earliest indications of Canaanite languages come from the few scattered alphabetic inscriptions beginning in the 18th century B.C., and from the 'Amarna letters,' Akkadian cuneiform clay tablets written by rulers of ancient Canaan (among others) to the pharaoh in Akhetaten, modern el-Amarna, in Egypt. Sometimes the Canaanite-speaking scribe glosses a word in his own language, using Akkadian syllabic writing just as he did for the lingua franca Akkadian in which the texts are mostly written; and this Akkadian itself is a mixed language with Akkadian vocabulary but the morphology and syntax of the local dialects of the scribes. There is enough evidence in the Amarna letters to identify the dialects of the Canaanite scribes as an early form of what later became Phoenician, Hebrew, and so on.

Phoenician is the name we give to the Canaanite language spoken in the cities of the northern coast of the Levant; modern scholars refer to the language as Phoenician after about 1200 B.C. This date marked a turning point in the region's fortunes, because it was approximately then that the so-called Sea Peoples, refugees from Mycenaean Greece, attacked Egypt, establishing a number of cities on the southern coast of the Levant and freeing the rest of Canaan from Egyptian control. (The most famous of the Sea Peoples are the Philistines.) Phoenician spread throughout the Mediterranean through the trading empire of the Phoenicians, and later the commercial empire of North African Carthage, originally an outpost of Levantine Tyre. Phoenician is a long-lived language: the first inscriptions long enough to analyze come from 10th-century Byblos, and in its Carthaginian extension (called Punic), the language is attested until the 4th century A.D., in Latino-Punic inscriptions. Phoenician and Punic texts are dedicatory, royal, funerary, votive, and commercial, plus a number of seals and coins.

Hebrew is the best-known Canaanite language because it was used to write most of the Hebrew Bible; because of its continued use as a literary language throughout Late Antiquity, the Middle Ages, and beyond; and because of its modern incarnation as the language of the modern state of Israel. Biblical or Classical Hebrew was the language of the ancient kingdoms of Israel and Judah in at least two dialects, Northern (or Israelian) and Judahite, from around 1200 B.C. to 600 B.C., when Judah was defeated by the Neo-Babylonian Empire. It is known from texts in the Hebrew Bible and from epigraphic remains and was written in the Hebrew script (developed from the linear Canaanite alphabet) right to left on various media, including stone, potsherds, and metals; no doubt the majority of ancient Hebrew texts were written on papyrus and are now lost to us. The few epigraphs that remain from this period are commercial, dedicatory, funerary, and administrative, plus a few seals and bullae (only a few that are surely authentic; forgeries abound).

It remained the spoken language of the area of those former kingdoms on some level, but exactly how central it was to most people is not clear, since Aramaic (see below) had taken over as the lingua

franca in the Near East as early as the 8th-century Neo-Assyrian Empire. Once Israel and Judah became provinces in the Assyrian, Babylonian, and Persian empires, most epigraphic evidence appeared in Aramaic, and the books of the Hebrew Bible that are written in that era, such as Daniel, Esther, and Chronicles, are written in Late Biblical (or Classical) Hebrew, a dialect or dialects that are either simply different from or developed from the Standard Biblical Hebrew of the earlier literature of the Bible. The extent of the differences is muted by the many editorial hands that have leveled the dialects in which the Hebrew Bible was written.

Middle Hebrew was the language of the several nationalistic revolts (under the Maccabees in the 2nd century B.C.; against the Romans, ending in 70 A.D.; and the Bar Kokhba insurrection ca. 135 A.D.) and it continued to be used in written texts from the 2nd century B.C. to the 5th century A.D., including the Hebrew texts from Qumran, Samaritan Hebrew, and the Mishnah. Medieval Hebrew continued the tradition of Middle and Classical Hebrew, both as a sacred and literary language, and as the language in which Jews from different countries could communicate. Modern Hebrew was revived as a spoken language in the 19th century and is still spoken today in the state of Israel.

Besides a few seals, Moabite is known from one reasonably long inscription, written on behalf of King Mesha to commemorate his military triumphs. It dates from the second half of the 9th century and is very much like Hebrew and Phoenician. The area of ancient Moab was in the southern part of modern Jordan. Ammonite and Edomite are known from only a very few inscriptions and seals, but as far as they can be analyzed, they, too, are very similar to the better-attested Hebrew and Phoenician. Ancient Ammonite was spoken in the central highlands of what is now Jordan, and Edomite was the language of the far south of Jordan.

Aramaic is distinguished from the rest of Northwest Semitic by its use of *-na* as the first-person plural suffix in all environments; by the change from vocalic *n* to *r* in the words for 'son,' 'daughter,' and 'two'; by its loss of the N-stem; and by the development of a new causative-reflexive stem **hittaqtal*, which replaces general Central Semitic **(v)staqtala*. Aramaic is divided into Old Aramaic, Official or Imperial Aramaic, Middle Aramaic, Late Aramaic, and Modern Aramaic.

Old Aramaic describes inscriptions from a number of closely-related dialects that date from the mid-9th century to the 6th century B.C. They are royal inscriptions, for the most part, but there is also a long treaty text, funerary inscriptions, religious texts, and a few seals, as well as other scattered pieces. Most are carved into stone in a 22-letter alphabet borrowed from the Phoenicians, written right to left, that is mostly consonantal, but even early on with indications of some long vowels.

Official or Imperial Aramaic was the lingua franca of the Persian Empire (from the 6th to the 4th century B.C.), and as such it spread west to Egypt and east as far as Pakistan. It survives in large numbers of papyri, especially from Egypt, where they have been protected by the dryness for millennia. The Aramaic of the biblical book of Ezra is Imperial Aramaic.

Known from the 3rd century B.C. to the 2nd century A.D., Middle Aramaic describes a large number of inscriptions written in a variety of dialects, such as Nabatean, Palmyrene, Hatran, and Old Syriac. Standard Literary Aramaic developed in Palestine and is the Aramaic of the biblical book of Daniel, of Targums Onqelos and Jonathan, of the Dead Sea Scrolls, the Bar Kochba letters, and quotations in the Mishnah and New Testament.

Late Aramaic begins in the 3rd century A.D. and includes Late Western Aramaic, Late Eastern Aramaic, and Literary Syriac. Late Western Aramaic is the language of the Palestinian Talmud, the Midrashim, and the Targums. It also includes Christian Palestinian Aramaic and Samaritan Aramaic. Late Eastern Aramaic is the language of the Babylonian Talmud. It also includes Mandaic and the language of a large number of incantation bowls from the 4th to the 7th century A.D. There is, finally, a huge Christian literature written in Literary Syriac from the 4th to the 13th century A.D. After the rise of Islam in the 7th century, Syriac was used less and less as a spoken language, but continued as the literary language of the Syrian Orthodox Church.

Modern Aramaic, or Neo-Aramaic, is still spoken by a few hundred thousand people from communities formerly situated in Iran, Iraq, and Syria for the most part; in recent decades, most of the speakers have left the Middle East and emigrated with their languages to the United States, Sweden, Germany, the Netherlands, and Australia, among others. Neo-Aramaic speakers are Christian, Muslim, Jewish, and Mandaean. The four main branches of Neo-Aramaic are Western (spoken in three villages near Damascus); Central (Turoyo and Mlahso, spoken in southeastern Turkey); Eastern (or Neo-Syriac, no relation to classical Syriac; spoken originally in Kurdistan); and Neo-Mandaic (spoken originally in western Iran).

There are some Northwest Semitic inscriptions that are difficult to identify as Ugaritic, Canaanite, or Aramaic. The dialect of the 8th-century B.C. prophetic inscription found at Tell Deir Alla in Jordan has been a matter of much controversy because it seems to

combine features of Aramaic dialects and of Canaanite dialects. The same is true to a lesser degree of the dialect of two 8th-century royal inscriptions from Zincirli in Turkey. It has been suggested that these inscriptions represent other forms of Northwest Semitic that did not hive off of the main branch at quite the same time as the three major languages.

Senegal: Language Situation

F Mc Laughlin, University of Florida, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Senegal is a country of approximately ten million people, located on the west coast of Africa in the arid Sahelian zone that lies south of the Sahara desert. Senegal shares a northern border with Mauritania, an eastern border with Mali, and a southern border with Guinea Bissau and Guinea Conakry. In addition, the small country of Gambia separates much of the northern part of Senegal from the south. The majority of languages spoken in Senegal are members of either the Atlantic or Mande families of Niger-Congo. Twenty or so indigenous languages are spoken in Senegal, quite a small number compared to the linguistic diversity of many other African countries. Six of these languages are legally classified as 'national languages.' These include Wolof, Pulaar (known elsewhere as Fula, Fulani, Fulfulde), Seereer, Joola, Soninke and Mandinka. The latter two are Mande languages while the former belong to the Atlantic family. In addition to the indigenous languages spoken in Senegal there are sizeable populations who speak Cape Verdean and other Portuguese superstrate creoles, and various dialects of Arabic. The largest populations of Arabic speakers are primarily of Mauritanian origin or of Syrian or Lebanese origin.

The Official Language versus the National Language

Superimposed on the mosaic of languages spoken in Senegal is French, the official language, the language of instruction in schools, and the language of the former colonial regime. While there are two important

Senegal: Language Situation

F Mc Laughlin, University of Florida, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Senegal is a country of approximately ten million people, located on the west coast of Africa in the arid Sahelian zone that lies south of the Sahara desert. Senegal shares a northern border with Mauritania, an eastern border with Mali, and a southern border with Guinea Bissau and Guinea Conakry. In addition, the small country of Gambia separates much of the northern part of Senegal from the south. The majority of languages spoken in Senegal are members of either the Atlantic or Mande families of Niger-Congo. Twenty or so indigenous languages are spoken in Senegal, quite a small number compared to the linguistic diversity of many other African countries. Six of these languages are legally classified as 'national languages.' These include Wolof, Pulaar (known elsewhere as Fula, Fulani, Fulfulde), Seereer, Joola, Soninke and Mandinka. The latter two are Mande languages while the former belong to the Atlantic family. In addition to the indigenous languages spoken in Senegal there are sizeable populations who speak Cape Verdean and other Portuguese superstrate creoles, and various dialects of Arabic. The largest populations of Arabic speakers are primarily of Mauritanian origin or of Syrian or Lebanese origin.

The Official Language versus the National Language

Superimposed on the mosaic of languages spoken in Senegal is French, the official language, the language of instruction in schools, and the language of the former colonial regime. While there are two important

factors that might seem to predispose Senegal towards widespread use of French, namely the nation's history as capital of the vast colonial territory of French West Africa and the intellectual legacy of former president, poet and member of the French Academy, Léopold Sédar Senghor, who promoted the use of French, its use in public and private life is considerably restricted. Instead, Wolof has become the nation's lingua franca, thanks in part to its having emerged as an urban language during the colonial period.

The spread of Wolof, which began during the colonial period, picked up momentum with the sustained migration of rural populations into the cities before and after independence in 1960. The social and economic influence of the Mouride Sufi order, whose origins are in the Wolof speaking heartland, have also encouraged the growing use of Wolof. Estimates indicate that while approximately 40% of Senegalese are ethnically Wolof, around 90% of the population use Wolof as a first or second language. Although it enjoys only co-equal status as an official 'national language' with the five other indigenous languages, Wolof is commonly, albeit informally, known as the national language of Senegal.

Urban Wolof

Wolof spoken in urban areas of Senegal has long been in contact with the official language, French. One of the consequences of this language contact is the emergence of an urban variety of Wolof, distinguished from its rural counterparts by large-scale borrowing of lexical items from French and a tendency to reduce the noun class system to a default class. Urban Wolof carries a certain prestige since it is associated with urban life and sophistication, but it is also looked down upon as a hybrid language whose speakers are unable to speak 'deep Wolof,' a Wolof free of loans.

Reactions to Wolofization

Wolof has varied sociolinguistic relationships with the five officially recognized languages, all of which are in some way influenced by the dominant position of Wolof on the national scene. Speakers of some of these languages share cultural as well as linguistic traits with speech communities outside Senegal. Pulaar is one of the western dialects of Fula, a language that has a vast geographic dispersion across west Africa, from Senegal, Guinea and Mauritania in the west to Cameroon and Chad in the east. Pulaar speakers consider their language to be a crucial aspect of their identity that links them to other Fula-speaking communities throughout West Africa. Likewise, Mandinka and Soninke are part of the Mande linguistic and cultural area that includes large parts of Mali, Guinea, Burkina Faso, Côte d'Ivoire and countries further afield. The transnational dispersion of these languages naturally plays an important role in how speakers view the spread of Wolof as a lingua franca. Seereer, on the other hand, is spoken almost exclusively in Senegal and Gambia, but Seereer ethnicity correlates with at least five different languages, thus language is less important as a marker of identity among this group who are generally also quite fluent in Wolof. Joola is spoken in Casamance, a region of the country that is culturally distinct from the area north of Gambia and which shares characteristics with the forest cultures of Guinea and Guinea Bissau. In addition, Casamance has been the seat of periodic secessionist uprisings that have fueled local sentiment against a heavily Islamized and Wolofized central government. Joola speakers are consequently not favorably presdisposed to the adoption of Wolof as a lingua franca, although Wolof has replaced Portuguese Creole as the main language of Ziguinchor, the main city of Casamance, within living memory.

Language and Religion

Religion – both majority Sufi Islam and minority Catholicism – plays an important role in Senegalese identity. The indigenous Senegalese Sufi order, that of the Mourides, has played an important role among its disciples in encouraging the use of Wolof as a religious language, whereas the other Sufi orders still grant such status to Arabic. Catholic populations, who are found primarily among the Joola and the Seereer, are more favorably disposed to the use of French.

Writing in Senegal

There are standardized writing systems for Senegal's national languages in the Roman script, but they are not widely used. Generally, those who write in the Roman alphabet write in French, while those who have not been educated in the French school system often keep records and write letters in their own language in the Arabic script. Since Koranic education is almost universal for Senegalese Muslims, rates of literacy in the Arabic script are no doubt quite high, although most measures of literacy only take writing in the Roman alphabet into account. Some contemporary writers such as Seex Aliyu Ndaw, Saxiir Caam, and Bubakar Bóris Jóob write in Wolof in the Roman script.

Sense and Reference: Philosophical Aspects

A Sullivan, Memorial University of Newfoundland, St John's NL, Canada

© 2006 Elsevier Ltd. All rights reserved.

The Origins and Central Core of the Sense/Reference Distinction

In his earliest works (e.g., Frege [1879]), Frege espoused a referentialist approach to language, according to which the meaning of an expression is whatever it is to which the expression refers. The referentialist picture is simple and compelling: singular terms such as 'Nancy' mean objects, general terms such as 'doctor' mean sets or properties, and the meaning of a sentence such as 'Nancy is a doctor' is the fact or state of affairs that the sentence is about.

Informative identity statements – i.e., true but nontrivial statements of the form 'a = b' – shattered this picture for Frege. His classic example is

(1) Hesperus is Phosphorus.

According to the lore, the Evening Star (the brightest heavenly body visible in the evening at certain times of the year) was baptized 'Hesperus,' whereas the Morning Star (the brightest body in the dawn sky at certain times) was baptized 'Phosphorus.' With the growth of astronomical knowledge, it turns out that Hesperus *is* Phosphorus, and what is more it is not a star at all but the planet Venus. The problem is to account for the difference between the meanings of (1) and

(2) Hesperus is Hesperus.

As (1) and (2) are constructed from co-referential parts, the referentialist approach seems to be committed to the view that they say exactly the same thing. However, according to Frege, there are substantive differences here: "'a = a' and 'a = b' are obviously statements of differing cognitive value; 'a = a' holds *a priori* ... while statements of the form 'a = b' often contain very valuable extensions of our knowledge and cannot always be established *a priori*" (1892: 175). Because referentialism cannot account for this evident fact about meaning, it is untenable, and a new view is wanted.

Frege's problem, then, is this: insofar as the function of a term is just to single out its referent, there is no way to distinguish the meanings of co-referential terms, and so no way to distinguish the propositions expressed by sentences that differ only in the interchange of co-referential terms. Frege's solution is that the semantic contribution of a term encompasses more than just its referent. 'Sense' is the name for the dimension along which the semantic contributions of co-referential terms can differ. Every term is associated with a sense, and the sense specifies the condition for being the term's referent. Co-referential expressions can have distinct senses, and expressions

Sense and Reference: Philosophical Aspects

A Sullivan, Memorial University of Newfoundland, St John's NL, Canada

The Origins and Central Core of the Sense/Reference Distinction

In his earliest works (e.g., Frege [1879]), Frege espoused a referentialist approach to language, according to which the meaning of an expression is whatever it is to which the expression refers. The referentialist picture is simple and compelling: singular terms such as 'Nancy' mean objects, general terms such as 'doctor' mean sets or properties, and the meaning of a sentence such as 'Nancy is a doctor' is the fact or state of affairs that the sentence is about.

Informative identity statements – i.e., true but nontrivial statements of the form 'a = b' – shattered this picture for Frege. His classic example is

(1) Hesperus is Phosphorus.

According to the lore, the Evening Star (the brightest heavenly body visible in the evening at certain times of the year) was baptized 'Hesperus,' whereas the Morning Star (the brightest body in the dawn sky at certain times) was baptized 'Phosphorus.' With the growth of astronomical knowledge, it turns out that Hesperus *is* Phosphorus, and what is more it is not a star at all but the planet Venus. The problem is to account for the difference between the meanings of (1) and

(2) Hesperus is Hesperus.

As (1) and (2) are constructed from co-referential parts, the referentialist approach seems to be committed to the view that they say exactly the same thing. However, according to Frege, there are substantive differences here: "'a = a' and 'a = b' are obviously statements of differing cognitive value; 'a = a' holds *a priori* ... while statements of the form 'a = b' often contain very valuable extensions of our knowledge and cannot always be established *a priori*" (1892: 175). Because referentialism cannot account for this evident fact about meaning, it is untenable, and a new view is wanted.

Frege's problem, then, is this: insofar as the function of a term is just to single out its referent, there is no way to distinguish the meanings of co-referential terms, and so no way to distinguish the propositions expressed by sentences that differ only in the interchange of co-referential terms. Frege's solution is that the semantic contribution of a term encompasses more than just its referent. 'Sense' is the name for the dimension along which the semantic contributions of co-referential terms can differ. Every term is associated with a sense, and the sense specifies the condition for being the term's referent. Co-referential expressions can have distinct senses, and expressions

need not have an actual concrete referent to have a sense.

The distinction between sense and reference is clearly illustrated in the case of a definite description, such as 'the tallest woman in Mongolia' or 'the architect who designed this building.' The sense is the identifying condition expressed by the term. It is that which must be grasped in order to understand the expression, and it is accessible to any competent speaker, regardless of whether they have been to Mongolia or seen this building. The referent is the individual that satisfies the condition that the sense specifies. Frege (1892) characterizes the sense as the mode of presentation of the referent. There are multiple ways of describing and conveying information about one and the same referent; and to each of these ways corresponds a distinct sense.

Frege's distinction generalizes well beyond cases like (1) and (2) – it is not limited to identity statements, or to singular terms. For example, (3) and (4) might differ in meaning, and (5) and (6) in truth-value, despite differing only in the interchange of co-referential terms:

(3) Hesperus is visible in the evening.

(4) Phosphorus is visible in the evening.

(5) The ancient Babylonians believed that Hesperus is visible in the evening.

(6) The ancient Babylonians believed that Phosphorus is visible in the evening.

Some related points are illustrated by sentences such as:

(7) Pegasus does not exist.

Such negative existential statements with non-denoting names in the subject-position pose problems for referentialism, as (7) is clearly meaningful despite the fact that its subject-expression does not refer to any actual thing. Furthermore, the same points apply to general terms. For example, to be a renate, one must have kidneys, whereas to be a cordate, one must have a heart. All and only renates are cordates, so the terms are co-referential; nonetheless, they clearly differ in meaning, and so are subject to the phenomena illustrated by (1)–(6). There are also non-denoting general terms – the term 'phlogiston', for instance, was introduced to name a substance given off in the process of fire. With the growth of knowledge, it turns out that there is no such thing, and so (8) poses problems for referentialism similar to those posed by (7):

(8) Phlogiston does not exist.

Frege concludes that, in general, the semantic contribution of an expression is not simply its referent. Instead, every significant linguistic expression has associated with it a sense that determines its referent. So, Frege's distinction amounts to a fully general approach to language that posits an intermediate layer of sense between words and referents.

More on Frege's Distinction

Frege's approach to the word-referent relation is a classic instance of what is called 'mediated' or 'indirect' reference – reference is *indirect* because there is a sense *mediating* the link between a term and its referent. The characteristic virtue of the indirect reference approach is that it affords a clear semantic distinction between co-referential expressions.

The distinction between sense and reference is a distinction between what we say and what we say it about. The sense of an expression is its contribution to the content of the thought or proposition expressed by uses of sentences in which it figures; the referent of an expression is its contribution to the truth-value of this thought or proposition. To illustrate, when enjoying a work of fiction, we are only engaged at the level of sense – "The thought [expressed by a sentence in the *Odyssey*] remains the same whether 'Odysseus' has a reference or not" (1892: 180). However, if we are interested in whether a thought is true, then we become engaged at the level of reference. "The question of truth would cause us to abandon aesthetic delight for an attitude of scientific investigation. . . . It is the striving for truth that drives us always to advance from the sense to the reference" (1892: 180). At the limiting case of a complete sentence, Frege takes its sense to be a thought or proposition, and its referent to be a truth-value (see Frege [1891, 1892] for further explanation).

Frege's individuates senses in terms of cognitive significance. Two statements differ in cognitive significance if it is possible for a competent speaker to take contrastive attitudes toward them (i.e., to believe that one is true while disbelieving, or withholding judgment concerning, the second). According to Frege, pairs such as (1)–(2) and (3)–(4) differ in cognitive significance. If two statements that differ only in the interchange of co-referential terms differ in cognitive significance, this proves that the terms differ in sense.

Consider again (3)–(6). Even though (3) and (4) differ in cognitive significance, they are nonetheless truth-conditionally equivalent, because they are built from co-referential parts. How then can (5) and (6) differ in truth-value, if truth-conditions are solely a matter of referents, not senses? Here Frege (1892) argues that in certain contexts (such as inside the scope of 'A believes that . . .') the referent of an expression is its customary sense. (5) and (6) assert

relations between agents and thoughts, not between agents and truth-values. They attribute distinct thoughts to the Babylonians, and thus can differ in truth-value.

Sense is that which links belief, meaning, and rational action. One might, for instance, believe that Hesperus is populated by an advanced and benevolent race and desire above all else to visit them, but still turn down a free trip to Phosphorus – and not be in the least bit irrational – as long as one does not believe that Hesperus is Phosphorus. Thus, senses are integral to the task of explaining and predicting rational action. Relatedly, merely identifying the referents of the expressions uttered is not sufficient for understanding what a speaker has said, on a Fregean view. (For instance, if one says 'Hesperus is Phosphorus,' to report or translate this utterance as saying that Hesperus is Hesperus is clearly unsatisfactory, even though it preserves truth-conditions.) To understand what has been expressed, one also needs to bear in mind the speaker's perspective on those referents.

Subsequent History, and Criticisms

Frege's distinction between sense and reference has had enormous impact on the subsequent development of the philosophy of language. Starting with Russell (1905), and continuing through seminal work by Davidson (1967), Kripke (1972), Putnam (1975), and Kaplan (1977), theorists begin their constructive projects by situating their theories in relation to Frege's. Furthermore, the influence of Frege's distinction is far from exclusively negative. There is a rich tradition, running through such influential theorists as Carnap (1947), Church (1951), and Montague (1974), which follows Frege's indirect reference approach in assigning two such semantic entities to every significant linguistic expression. Down this path, Frege's distinction had a direct influence on the development of more or less every single branch of intensional logic and semantics.

More generally, Frege's distinction is now pervasive throughout philosophy, a part of the canon. Whether the topic be ontology, minds, or morals, in any case in which it is important to bear in mind subtle distinctions between conceptual conditions and that which satisfies those conditions, one is likely to encounter the sense/reference distinction. (This is clearly illustrated in recent philosophy of mind, in which finessing the distinction between the sense and the reference of psychological [qualitative, phenomenal] terms is – interestingly, and tellingly – a core part of the arguments of both dualists [cf. Chalmers (1996)] and the physicalists who oppose them [cf. Papineau (2002)].)

There are, however, many critical questions raised by Frege's distinction between sense and reference. For one thing, positing senses gives rise to difficult metaphysical questions, such as: 'What, exactly, are senses?' Frege (1892, 1918) gives arguments about what senses are not – because co-referential expressions can differ in sense, senses are not of the physical realm; since distinct mental states can have exactly the same sense, senses are not private mental entities. However, as for what senses are, exactly, Frege (1918) just offers a vague metaphor: senses exist in some third realm, distinct from the physical and mental realms. Understandably, many find this 'third realm' talk to be beyond belief. At best, it is in need of significant clarification.

Some of the most influential objections to Frege's distinction were raised in the 1970s – led by Donnellan (1970), Kripke (1972), Putnam (1975), and Kaplan (1977). One way to put their basic thrust is this: two central constraints on senses are that they be answerable to concerns of cognitive significance and that they be objective; however, there is something subjective, or speaker-relative, about cognitive significance. (For example, two competent speakers could disagree as to whether it is significant or trivial to be told that Homer is the author of the *Odyssey*; and it is not evident that there are any objective grounds that would conclusively resolve such a dispute.) Thus, these two constraints pull in opposite directions, and it is not clear that any one thing can satisfy them both. More generally, the aforementioned articles give reasons to be skeptical as to whether expressions have one determinate objective sense, and, even if so, reasons to be skeptical as to whether this sense determines reference.

Led by Dummett (1981), Evans (1982), and McDowell (1986), neo-Fregeans have sought to defend refined interpretations of Frege's doctrines from some of these objections. (One of the core ideas is that many criticisms of Frege's views can be met if senses are conceived as object-dependent – and so 'rigid,' in Kripke's [1972] terminology.) In the other direction, original criticisms of Frege's approach continue to surface. (For an important example, see Schiffer's [1992] argument that nothing can satisfy the demands that Frege places on the notion of 'sense'.) In any case, it is evident that Frege's problem does pose a challenge to many views of meaning and reference, and that there is some aspect of meaning, distinct from reference, that is essential to understanding rational thought and intentional action. Exactly what Frege's problem shows, or exactly how to characterize the latter aspect of meaning, though, are complex matters that remain controversial.

Sentence Fragmentation: Stylistic Aspects

C Emmott, A J Sanford and L I Morrow, University of Glasgow, Glasgow, UK

The Study of Sentence Fragmentation in Written Texts

The term 'sentence fragmentation' refers here to the use of linguistic expressions that are not grammatically full sentences but that are nevertheless punctuated like sentences. This article focuses on how fragmentation is used for stylistic purposes in written texts. The examples are drawn primarily from literary texts, but fragmentation is nevertheless also used in many other types of written texts, including newspaper articles, advertisements, and popular science writing.

Sentence fragmentation attracted interest in the early days of modern stylistics as part of the study of sentence length. Crystal and Davy (1969) examined fragments in spoken discourse and a range of written texts, using the term 'minor sentence.' Crystal and Davy made a distinction between 'minor sentences' and 'ellipses' of major sentences, arguing that "there is no intuitively clear relationship between a minor sentence and a corresponding major version, and in many cases it is impossible to say what in fact was the form of the major sentence from which the minor sentence was supposed to have been derived" (1969: 51). Leech and Short (1981: 217) continued the stylistic analysis of fragmentation in their study of prose fiction, arguing that the punctuation of fragments provides additional emphasis and can suggest "the rhythm and intonation one would use in reading the texts aloud." According to their discussion, fragments are graphological sentences but not syntactic sentences. In both these classic stylistic studies, the term 'sentence' was retained, whereas we prefer to give priority to the syntactic definition of the sentence and hence see these items as fragments of sentences, not as a type of sentence.

Since these early studies, stylisticians have continued to observe sentence fragmentation in the process of performing their analyses of specific texts. The study of fragments is hence an accepted part of any stylistician's 'tool kit' of techniques of analysis and so is of general interest within stylistics. However, as a topic of study in its own right, fragmentation has been of most interest to those stylisticians

Sentence Fragmentation: Stylistic Aspects

C Emmott, A J Sanford and L I Morrow, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

The Study of Sentence Fragmentation in Written Texts

The term 'sentence fragmentation' refers here to the use of linguistic expressions that are not grammatically full sentences but that are nevertheless punctuated like sentences. This article focuses on how fragmentation is used for stylistic purposes in written texts. The examples are drawn primarily from literary texts, but fragmentation is nevertheless also used in many other types of written texts, including newspaper articles, advertisements, and popular science writing.

Sentence fragmentation attracted interest in the early days of modern stylistics as part of the study of sentence length. Crystal and Davy (1969) examined fragments in spoken discourse and a range of written texts, using the term 'minor sentence.' Crystal and Davy made a distinction between 'minor sentences' and 'ellipses' of major sentences, arguing that "there is no intuitively clear relationship between a minor sentence and a corresponding major version, and in many cases it is impossible to say what in fact was the form of the major sentence from which the minor sentence was supposed to have been derived" (1969: 51). Leech and Short (1981: 217) continued the stylistic analysis of fragmentation in their study of prose fiction, arguing that the punctuation of fragments provides additional emphasis and can suggest "the rhythm and intonation one would use in reading the texts aloud." According to their discussion, fragments are graphological sentences but not syntactic sentences. In both these classic stylistic studies, the term 'sentence' was retained, whereas we prefer to give priority to the syntactic definition of the sentence and hence see these items as fragments of sentences, not as a type of sentence.

Since these early studies, stylisticians have continued to observe sentence fragmentation in the process of performing their analyses of specific texts. The study of fragments is hence an accepted part of any stylistician's 'tool kit' of techniques of analysis and so is of general interest within stylistics. However, as a topic of study in its own right, fragmentation has been of most interest to those stylisticians

who focus specifically on the form of literary texts (a to d) and those who work on types of text that make heavy use of fragments (e, for example).

a. Stylometry: Within the area of 'literary and linguistic computing,' there is an interest in the use of the computer to 'measure' style, termed 'stylometry.' The average length of sentences is studied, and there is particular interest in the range from those that are 'monumental' in length to extremely short sentences, including sentence fragments (Barr, 2001). This type of analysis is used particularly in cases of disputed authorship but can also be used to assess stylistic differences between authors.
b. Iconicity studies: In this area, the interest is in the nature of the linguistic sign. Iconicity specialists suggest that form might 'mime meaning,' rather than the sign's being arbitrary (e.g., Nänny and Fischer, 1999). The study of iconicity includes the study of sentence length (e.g., Müller, 1999). Fragmentation is of relevance here because the heavy punctuation can be used to create 'mimicking' effects such as indicating speed or slowness of movement (see the section 'Summary of Major Stylistic Functions of Fragmentation in Literary Texts').
c. Bibliography: In this area, the interest is in the physical presentation of a text, i.e., its editing and printing. Punctuation is studied for its role in the layout of the text (e.g., Bray *et al.* [eds.], 2000) and because it is an aspect of the text that often gets changed in the editing process, sometimes affecting the author's intended meaning (see, for example, Sotirova, 2002, for a study of editorial punctuation changes in D. H. Lawrence's work).
d. Poetry and verse drama: Sentence fragmentation is important in poetry and verse drama, since it affects the line length and rhythm of the verse (e.g., Leech, 1969: 47–48; Nänny, 2001).
e. Representation of speech and thought in narrative texts: Sentence fragmentation is recognized as being a key method of representing speech and thought in the novel (Leech and Short, 1981; Fludernik, 1993). In direct speech, the fragmentation could perhaps be argued to suggest the natural rhythms of real speech, although stylisticians are extremely cautious about making any claims of this type, since represented speech is quite different from a transcription. The interest in fragmentation in thought owes much to studies of 'stream of consciousness' writers, such as James Joyce, but fragmentation can nevertheless be found in a much broader range of writers, as illustrated in the section 'Types of Fragmentation.'

Beyond stylistics, fragmentation is also a concern of writers of style manuals (e.g., punctuation guides and books intended to train the novice writer about 'good' style). Traditionally, writing style manuals have warned novice writers against producing fragments, but there is nevertheless a tendency nowadays to acknowledge that there are special stylistic uses of this type of writing in literary texts (e.g., Allen, 2002: 57; King, 2004: 13–14).

Fragmentation is sometimes referred to in grammar textbooks, but the handling of this topic is often rather brief, peripheral to the main grammatical discussion of these books, and certainly does not reflect the diversity of use of fragments in written texts. Quirk *et al.* (1985: 1446) discuss the topic in a section on prosody and punctuation in their chapter 'From sentence to text.' They contrast 'I saw Miriam and Walter.' with 'I saw Miriam. And Walter.', arguing that the first suggests a couple who regularly appear together, whereas the second might suggest either that Walter is being mentioned as an afterthought or that the sight of him is being given special or dramatic significance. Quirk *et al.* claim that these two very different interpretations are context dependent and have different prosodies attached to them in reading (including silent reading). They regard the punctuation of the fragments as 'unconventional' and suggest that novelists and poets are more likely than ordinary writers to use such punctuation, yielding prosodic interpretations of their works. Huddleston and Pullum (2002: 944–945) use the term 'minor clause types' to cover exclamations and fixed phrases (e.g., 'On with the show!' and 'Like father, like son.'). In their section on punctuation, Huddleston and Pullum (2002: 1735) recognize one specific type of fragmentation that occurs in connected prose, the splitting of a single sentence into two separate components (e.g., 'He had broken the vase. Deliberately.'). This type of structure is covered in 'Types of Fragmentation' (see discussion of Type 5 fragments). Huddleston and Pullum's explanation is in terms of information packaging, suggesting that the punctuation gives extra importance to the latter element in the same way as prosody could set it apart in speech. They also argue that brevity might be a consideration and might explain the use of fragments in journalism. These discussions of fragmentation in writing have shown an awareness of parallels with spoken discourse. Fragmentation has attracted greater interest among those grammarians and discourse analysts working on the differences between speech and writing (e.g., Miller and Weinert, 1998; Biber, 1988; Biber *et al.*, 1999), sometimes causing them to question whether the sentence as a unit has significance in spoken discourse (e.g., Miller and Weinert, 1998; Sornicola, 1981).

In psychology, the study of sentence fragmentation has relevance to research on sentence complexity. There is a growing body of empirical research on

'depth of processing' that shows that readers are less attentive to errors or changes in a text when information is embedded in complex structures, such as subordinate clauses, rather than in main clauses (see Sanford and Sturt, 2002; Sturt *et al.*, 2004). On this basis, fragments might be predicted to increase attention due to their brevity and simplicity and also to their ability to extract information that might otherwise have appeared within an earlier full sentence. We have investigated the functionality of short fragments as part of the Glasgow LINCS Project (Literature, Narrative and Cognitive Science: Interdisciplinary Perspectives on the Nature of Reading). In one experiment (Emmott *et al.*, 2004), readers saw a variety of passages, including critical phrases presented in three possible settings: (a) as sentence fragments in their own paragraphs, (b) as sentence fragments not in their own paragraphs, or (c) as part of a preceding sentence. The passages were presented not once but twice, in close contiguity, and sometimes a word was changed in the critical phrase to one that was different but of similar meaning. The task was to indicate any changes that might have occurred. It was found that more changes were detected when the critical phrases were not part of another sentence but stood alone. However, it did not matter whether the fragments were in their own paragraphs or not. These results show that short fragments serve to grab attention and lead to more substantial processing than do (identical) phrases in longer sentences, thus confirming one of the primary assumptions made in the stylistic analysis in the next section.

Types of Fragmentation

In the stylistic work described earlier, there has been interest in fragmentation, but little systematic exploration of the different types of fragmentation. In this section we provide examples of 16 types of fragmentation found in our database of examples collected and categorized for the Glasgow LINCS Project. The list is not intended to be fully comprehensive at this stage but nevertheless shows the wide range of different uses of fragmentation. The source texts are mainly narrative fiction but also include two autobiographies (examples [2b] and [16a]) and two popular science texts (examples [9b] and [16b]). The fragments under discussion (and occasional short elliptical expressions) are indicated with bold underlining, and other items that are particularly relevant to the stylistic analysis are marked in bold. For all of the examples discussed here, the stylistic interpretations are subjective literary–linguistic judgments and would need to be tested empirically to show whether the fragments are interpreted by readers in the ways suggested (only the effect on attention has been tested so far, using Type 4 fragments).

Type 1: Echoic Fragments (I): Direct Repetition

Fragments can directly repeat an element of the previous sentence or an earlier sentence. This can be used to represent a character's reviewing his or her own thoughts or reacting to the speech of another character.

(1a) On the kitchen door, up behind Mattie, was **a quilted Christmas tree** that had been bought at **a church Christmas fair** years ago [. . .] **Christmas.** A subject Kathryn didn't want to think about hovered at the edges of her brain, like a dull headache. (Shreve, *The Pilot*'s *Wife,* p. 87; our ellipsis)

(1b) 'Oh,' she said quickly, 'I think **my Evan** would mind. He would not like to sleep without me.' **My Evan.** (Shreve, *The Weight of Water,* p. 228)

The fragmentation in (1a) allows the focalizer to reflect on an aspect of the situation and then use it as a topic for further discussion (the fragment is Type 1 in terms of echoing previous information and Type 12, discussed later, in terms of specifying a new topic). This provides an effective representation of the 'double take' of the recently bereaved focalizer as she views the decorations around her and reacts to their inappropriateness in her new situation. The fragmentation allows the word 'Christmas' to switch from a modifier to a headword, facilitating this change of direction.

Example (1b) shows the focalizer reacting to the direct speech of another character. The words 'my Evan,' spoken here by Evan's new wife, are subsequently echoed in the following line in the mind of his sister, the focalizing character, reflecting her difficulty in coming to terms with his recent marriage due to her own previous close relationship with him. Examples (1a) and (1b) require 'text world' knowledge (Werth, 1999; see also Emmott, 1997) of the relevant situations in the stories in order to clarify the significance of the fragments.

Type 2: Echoic Fragments (II): Repetition with Expansion

A particularly common pattern is for the fragment to repeat a specific element of the previous text (usually the previous sentence) with an extra word or words added.

(2a) The car is in a **driveway. A familiar driveway.** (Shreve, *The Pilot*'s *Wife*, p. 45)

(2b) I had cancer. **Stage III ovarian cancer.** (Tilberis, *No Time to Die*, p. 15)

(2c) That would have been **unbearable. Literally unbearable.** (Shreve, *The Pilot*'s *Wife*, p. 127)

(2d) For **seven months** she had been ripening, like a mango on a tree. **Only seven months.** (Ali, *Brick Lane*, p. 11)

The additional wording in the fragments may have a wide range of functions, some of which are illustrated here. In (2a) and (2b), the extra words provide additional information. In (2c), the fragment has an intensifying function, reinforcing the validity of the assertion. Sometimes the added element focuses on a specific detail of the previous sentence to make the significance of that information clear. So in (2d), which relates to a woman's suddenly giving birth, the fragment highlights the unusually short duration of the pregnancy.

Type 3: Additional Information without Repetition

The repetition in (2a) and (2b) is a common way to present extra information in a fragment, but additional information can also be presented without the repetition as in (3):

(3) He holds a watch in front of her face. It swings to and fro on a chain. **Gold or brass, perhaps, beautifully polished.** (Galloway, *Clara,* p. 19)

Type 4: Greater Specificity: Identification of an Under-specified Referent or Clarification of Function

(4a) **Something** was digging sharp into the soft flesh at the small of my back. I shifted a little. **A hairpin**. (Welsh, *The Cutting Room,* p. 115)

(4b) At a little wash-hand stand at the foot of the bed there was **another figure. Walter**. (Waters, *Tipping the Velvet,* p. 167)

(4c) But no, he's reaching into his pocket and now he's releasing **two coins** onto the table. **The tip**. (Shields, *Unless,* p. 34)

In (4a), there is a cataphoric relation, with the referent initially being under-specified by an indefinite pronoun and then the identification being provided in the fragment. This reflects the gradual process of discovery of a focalizing character as she identifies the source of a tactile sensation. Example (4b) is similar, but with initial under-specification by means of a general noun phrase rather than a pronoun. The initial under-specification builds up suspense about a character who appears unexpectedly in a situation, leading us to wonder initially who the person is. Example (4c) is rather different, since the coins are clearly identified, but the fragment provides an indication of their function in this context.

Type 5: Fractured-Off Components

In certain cases, the fragment could have been part of the previous sentence, but the overall structure has been fractured into a grammatically complete sentence and one or more fragments (e.g., [5a] and [5b]). The 'fractured-off' component can also follow an 'and-clause' (e.g., [5c]) or follow another nonclausal fragment (e.g., [17], discussed later).

(5a) The whole combination would melt his bones into jelly. **Inch by inch**. (Dick, *Ubik,* p. 146)

(5b) In all her eighteen years, she could scarcely remember a moment that she had spent alone. **Until she married**. (Ali, *Brick Lane,* p. 24)

(5c) And she died. **At forty three**. (Lively, *The Photograph,* p. 45)

Often these 'fractured-off' fragments are manner and time adverbials, as shown in (5a) to (5c), but other grammatical structures are possible, such as the relative clause in (17).

The interpretation of the fragmentation depends on the specific example. In (5a), the fragmentation intensifies the manner of the horrific event. The fractured-off time adverbial in (5b) is deeply ironic, since we would expect marriage to bring companionship, not loneliness – this nevertheless reflects a key aspect of this character's life and a key theme of the book. Example (5c), like (5b), separates off a time adverbial in order to highlight the surprisingly early age of death.

Type 6: Isolated Connectives

In some cases, connectives are isolated entirely from the surrounding text, generally providing either a strong contrast or addition.

(6a) By *play*, she meant *work*, which was what *play* meant, had always meant. **But**. (Galloway, *Clara,* p. 176; Galloway's italics)

(6b) I think it is time I retired into respectability. ***And***. If you cannot see that Ricky has four or five times your significance, then you are deluding yourself. (Peter Straub, *Ghost Story,* p. 335; Straub's italics. Cited by Quirk *et al.*, 1985: 1446)

Quirk *et al.* discuss (6b), arguing that the fragment's occurrence in direct speech reflects the prosody of real speech. (Straub's italicization, ignored in Quirk *et al.*'s citation of the example and their discussion of it, is also significant in this respect.)

Connectives can also occur with topic indicators (Type 12), as shown in (6c).

(6c) Most memory is friable as dust and no one can be expected to remember everything. **Dresden,**

however. She may admit recalling a visit to Dresden [. . .] (Galloway, *Clara,* p. 66)

Type 7: Incomplete Narration

This type of fragmentation suspends the narrative and can leave important information unexpressed, as in (7). This type of example is uncommon in the texts we have examined, but it is of particular stylistic interest.

(7) Most of all, Nick finds himself plunged suddenly into endless replays of Glyn's voice. Not only now, but back then. **That day**. **When Kath**. (Lively, *The Photograph*, p. 204)

The reader of the novel can infer from their 'text world knowledge' that the final fragment refers to 'When Kath died.' The incomplete expression gives the impression of Nick's inability to reflect on Kath's death, imitating his 'mind-style' (Fowler, 1986/1996). The following chapter (starting on the page after this example) uses one of these fragments, 'That day,' as its heading and then looks in more detail at the circumstances of the death, revealing that the final fragment in the above example might more accurately read 'When Kath committed suicide.' Hence, the fragments have plot significance as well as reflecting the character's style of thinking.

Type 8: Similarity: Paraphrase, Semantic/Pragmatic Connection

In some cases, the fragment is a paraphrase or rough paraphrase of an element in a previous sentence or a previous fragment, as in (8a) and (8b).

(8a) On her way home that evening, she felt **troubled**, she says. **Unsettled**. (Heller, *Notes on a Scandal*, p. 49)

(8b) It couldn't be suicide, Kathryn thought. Suicide was absolutely impossible. It was **unimaginable. Unthinkable**. **Out of the question**. (Shreve, *The Pilot's Wife,* p. 79)

Sometimes the fragment can go beyond paraphrase and provide a semantically or pragmatically-related reformulation:

(8c) [. . .] I meant to write **a jokey novel. A light novel. A novel for summertime, a book to read while seated in an Ikea wicker chair with the sun falling on the pages as faintly and evenly as human breath.** (Shields, *Unless*, p. 14)

In (8c), the different ways of describing the novel do not mean exactly the same thing, but they nevertheless specify roughly the same type of novel in this context. In some cases, the relation may be specific to the ideology and/or special mind-style of the focalizer and so may not be generally accepted as related (as illustrated in [17]).

Type 9: General–Particular and Hypothetical–Real Relations

A common pattern in texts is the general–particular relation (Hoey, 1983; see also Mann and Thompson, 1988). Example (9a) illustrates this, with the fragment giving a specific example of an item in the category of gifts mentioned in the previous sentence. Example (9b) shows how this type of relation is characteristically used in expository writing, here providing a negative contrast between the actions of the general category of scientists and the actions of this particular scientist. Example (9c) represents Archie as a particular instance of the general category 'a man as average as this,' but the contrast is between Clara's hypothetical notion of how Archie should behave and the real Archie's behavior, hence a hypothetical–real relation (Hoey, 1983; Winter, 1986).

(9a) Now, how do the young prepare to meet the old? [. . .] with the feeling that they must arrive with something the other will like, something suitable. **Like Garibaldi biscuits**. (Smith, *White Teeth,* p. 162)

(9b) Some lab scientists killed the frogs after cutting them open to remove their eggs. **Not Zasloff**. (Shnayerson and Plotkin, *The Killers Within: The Deadly Rise of Drug-Resistant Bacteria,* p. 217)

(9c) And if you are saddled with a man as average as this, Clara felt, he should at least be utterly devoted to *you* – to your beauty, to your youth – that's the *least* he could do to make up for things. **But not Archie**. (Smith, *White Teeth,* p. 48; Smith's italics)

Type 10: Evaluations, Conclusions, and Comments

Fragments often provide an evaluation, a conclusion, or a comment representing the reaction of a focalizing character to a particular situation. Examples (10a) and (10b) show the narrative of the first sentence in each case leading into the thoughts of the character, thereby providing an evaluation and inference respectively (see also [21] and [22] for evaluations and a summary respectively). Example (10c) is more generally descriptive, and the fragmentation highlights the rather paradoxical conclusion.

(10a) He looks up from the spread photograph and stares out of the window struck by this. **Odd**. (Lively, *The Photograph,* p. 20)

(10b) He listened to the ringing tone for a minute or so then hung up. **Gone out, presumably**. (Lively, *The Photograph,* p. 208)

(10c) It was like curing a case of tapeworm by starvation. **Entirely possible, and unavoidably lethal**. (Ali, *Brick Lane,* p. 131)

Type 11: Repairing and Reworking – Negation, Correction, Qualification, and Uncertainty

Fragments can be used to repair or otherwise rework a previous statement, as in (11a) to (11e).

(11a) **A body** spinning in the air. **No**. **Not even a body**. (Shreve, *The Pilot*'s *Wife*, p. 18)

(11b) They lived in cheerful **squalor. Or not squalor: disorder**. (Atwood, 'Weight' in *Wilderness Tips*, p. 182)

(11c) If it was counsellors, the waitresses would giggle more, preen more, arch their backs. **Or some of them would**. (Atwood, 'True Trash' in *Wilderness Tips*, p. 11)

(11d) It is a decisive journey. **For me, at least**. (Walker, *Blackbox*, p. 1)

(11e) Mother was a woman with **brown** hair. **Reddish perhaps**. **Light ash**. (Galloway, *Clara*, p. 124)

The fragment in (11a) negates the existence of the entity in the previous sentence, showing the focalizing character's revised perception of a situation. Example (11b) shows a shift in wording that offers a different perspective on the previous statement. The fragments in (11c) and (11d) do not negate their previous sentences but qualify their assertions. In (11e), the fragments provide alternative possibilities due to the uncertainty of the focalizing character.

Type 12: Topic Management and Orientation

Fragments can introduce a new topic or subtopic for discussion, as in (12a) and (12b) (see also [1a] and [6c]). Fragments can also consist of orientation signals that provide time and/or place information as a new section of a narrative starts, as in (12c). These orientation signals sometimes serve as topic indicators in addition to specifying the spatiotemporal coordinates. In (12c), there is some subsequent discussion of the garden opening festival, before the events on that occasion are described.

(12a) She tried to single out a thought, any thought, and take charge of it. **The children**. How could she present the girls with a new father like that? (Ali, *Brick Lane*, p. 404)

(12b) I was thinking quickly. **Drugs**. Some awful mix-up with drugs. **Or a cult**. I tried to picture cult members I'd seen hanging around the university, grey robes, sandals. (Shields, *Unless*, p. 132)

(12c) **Saturday**. **Garden opening day**. And it is all that was promised by the weather forecasters: Wedgwood-blue summer sky with trails of rippling cirrus, warm sunshine, the lightest of breezes. (Lively, *The Photograph*, p. 158)

Type 13: Discovered/Noticed Objects, Impressions, and Memories

Fragments can often reflect the observations of a focalizing character, sometimes individual items, but often in list form. These observations may be of items discovered or noticed by a character, as in (13a). Observations may also be impressions that have been made on the focalizer over a space of time. In (13b), the sounds are not necessarily observed on a single occasion. In (13c), the impressions are a bereaved son's memories of his father (extracted from a longer list of fragments in the original text). These impressions include Type 1/2 echoic items ('His face.'; 'And again, his face.'). Some of the expressions in (13b) and (13c) might more accurately be described as elliptical sentences rather than sentence fragments (see 'Future Linguistic and Stylistic Research').

(13a) She felt around in the pockets of her parka. **A used Kleenex**. **Coins**. **An outdated credit card**. **A couple of dollar bills**. **A tube of Lifesavers**. (Shreve, *The Pilot*'s *Wife*, p. 128)

(13b) If she put her ear to the wall she could hear sounds. **The television on**. **Coughing**. **Sometimes the lavatory flushing**. **Someone upstairs scraping a chair**. **A shouting match below.** (Ali, *Brick Lane,* p. 24)

(13c) **Watching him play tennis**.
The way his knees sometimes buckled when he walked.
His face.
His resemblance to Abraham Lincoln, and how people always remarked on it.
His fearlessness with dogs.
His face. And again, his face. (Auster, 'Portrait of an invisible man,' p. 29)

Type 14: Narrated Action Sequences

Fragments can represent action sequences, as in (14a), where the sequence might be viewed as iconically reflecting the speed of movement and/or the fact that the character is probably out of breath so communication in full sentences is impaired. The manner of performing actions can also be represented in fragments (see [24]). In (14b), the recurrence of an action is iconically represented by fragments that count the actions.

(14a) Nazneen ran. Down Bethnal Green Road. **Turned at Vallance Road. Jogged down New Road. Stitch**

in her side on Cannon Street. (Ali, *Brick Lane*, pp. 466–467)

(14b) While Archie and Samad assessed this situation as best they could, Colonel-General Jodl sat in a small red schoolhouse in Reims and shook his fountain pen. **Once**. **Twice**. (Smith, *White Teeth,* p. 92)

There is some overlap between Types 13 and 14. Impressions and memories (Type 13) can include impressions and memories of actions, as in (13b) and (13c). Also, movement can underlie sequences of impressions, as in (23), where we see the observations of a focalizing character as she speeds across town in an ambulance.

Type 15: Brevity of Direct Speech

Direct speech in fiction mimics real speech by presenting brief phrases that rely on contextual information for their interpretation. In some cases, the meaning might be inferred from an earlier utterance or from the physical context of the characters, and so might be regarded as elliptical rather than fragmentary (Huddleston and Pullum, 2002: 1541–1542; Biber *et al.*, 1999: 1099). In (15), the context is set up by the earlier episode in which Samad decides what to bring as a gift. In addition to representing the brevity of speech, the identification of the coconut provides a Type 4 clarification of a previously underspecified object, the surprise effect being accentuated by the intervening ellipsis between episodes.

(15) Alibi done, three minutes were left for Samad to consider what an old man brings a young girl [. . .]; something suitable . . .
'A coconut?'
Poppy Burt-Jones took the hairy object into her hands and looked up at Samad with a perplexed smile. (Smith, *White Teeth,* p. 166; our ellipsis followed by Smith's ellipsis)

Type 16: Interactive Components: Metalinguistic Items and Dialogic Responses

Fragments can be used for metalinguistic items employed on occasions where the narrator suddenly comments on his/her own narrative style, as in (16a). Fragments are also common in the heavily rhetorical use of answers provided in response to an author or narrator's own questions. Example (16b) provides an example from a popular expository text, and (16c) is from a literary text.

(16a) **Enough rambling**. (Bauby, *The Diving-Bell and the Butterfly*, p. 13)

(16b) It sounds like it should be a winner, right?
Wrong. (Gladwell, *The Tipping Point*, p. 114)

(16c) His solution? **To refuse sleep**. (Galloway, *Clara*, p. 107)

Summary of Major Stylistic Functions of Fragmentation in Literary Texts

Speech and Thought Representation

Fragmentation has been recognized as being particularly important in the representation of speech and thought in literary texts (e.g., Leech and Short, 1981; Fludernik, 1993). It is very common in direct speech and has the role of making the speech appear realistic (although, as discussed earlier in this article, there is a considerable difference between fictional direct speech, designed to be easily readable, and a transcript of real speech) and may also be used to indicate rhetorical emphasis by the speaker. In narrative texts containing a lot of direct speech and in drama texts (where direct speech is the main medium of communication), fragmentation might perform a much broader range of functions (this would need further investigation; see the section 'Future Linguistic and Stylistic Research'). As far as thought presentation is concerned, fragmentation can signal switches from main narrative to represented thought and hence indicate crucial changes of perspective. Some of the types of fragmentation listed in the previous section are particularly well suited to represent thought in fiction. Echoic fragments (Types 1 and 2) enable a character to think over his or her own thoughts again or to react to the speech or thoughts of another. They can also reflect the pervasiveness of a particular memory (13c). Fragments that provide greater specificity (Type 4) enable a character to gradually realize details of his or her surroundings, which is very different from the more factual presentation style of an omniscient narrator. Paraphrase and semantic/pragmatic connections (Type 8) can give the sense of a character's pondering over a topic, as in (8b). Evaluations, conclusions, and comments (Type 10) show the character's perspective on the events that are occurring. Repairs and reworkings (Type 11) enable a character to revise or modify his or her view as the text progresses, or they can reflect uncertainty. Topic management fragments and orientation fragments (Type 12) guide the character's thoughts and make the direction of the thoughts clearer to the reader. Observations, impressions, and memories (Type 13) are the basic material of stream of consciousness fiction.

Fragmented thought can help convey a particular mind-style. This has already been discussed in relation to example (7), where incomplete narration (Type 7) reflects a bereaved character's inability to

think through the details of the day of death. Sometimes connections made can be idiosyncratic to the focalizer. Hence, in (9a), the children selecting the gift are wrong in their assumption that the old person in question will like Garibaldi biscuits, since we later discover that he has no teeth to eat them with. Example (17) reflects the distinctive ideology of a particular focalizing character, the father of the 'inattentive daughter.'

(17) Only an inattentive daughter could fail to see. **A disrespectful daughter. Who fully deserved the lashing, verbal or otherwise, that followed such dereliction of duty**. (Ali, *Brick Lane*, p. 205)

The fragment 'A disrespectful daughter.' may be connected (Type 8) in the mind of the focalizer, but there is nevertheless a leap between this and the notion of 'inattention.' The 'fractured-off' (Type 5) relative clause that follows it highlights a rather dubious logic that may be held by the character but will not necessarily be held by the reader.

Fragments may also be used as part of the stylistic technique of 'defamiliarization' (Shklovsky, 1965 [1917]), the way in which the familiar is 'made strange.' In (18), the defamiliarization reflects the focalizer's unusual perception when she is having a tooth extracted at the dentist.

(18) The bones in his hand were bruising her lip. And that sound of the gum tugging back from what he was doing, **the jaw** creaking. **Her jaw**. (Galloway, *Blood*, p. 1)

Here, the focalizing character hears the sound of the creaking jaw but acknowledges only in the final fragment that the sound is coming from her own body.

Rhetorical Functions

The examples in the section 'Types of Fragmentation' illustrate a broad range of rhetorical functions. Type 2 allows extra emphasis by repeating and modifying a phrase, and Type 5 enables a part of a sentence to be highlighted by segmenting it from the previous sentence. The Type 6 isolated connectives enable strong contrasts and additions to be made. Relations such as similarity (Type 8), general–particular (Type 9), and hypothetical–real (Type 9) are a crucial part of the basic rhetorical structure of a text (Hoey, 1983; Winter, 1986; Mann and Thompson, 1988), together with text components such as evaluations (Hunston and Thompson [eds.], 2000). Topic management and/or orientation enables a text to be organized at a higher topic or episode level. The interactive components provide heavily rhetorical elements such as answers to rhetorical questions.

In certain cases, a fragment can signal a major change in the rhetorical direction of a passage, as in (19).

(19) The Scheme for Full Employment was the envy of the world [. . .] Planned to the finest detail by people of vision, The Scheme was watertight, and could not possibly go wrong.
Except in this country.
In this country we managed to destroy it. (Mills, *The Scheme for Full Employment*, unnumbered preface)

Here the fractured-off item (Type 5) provides a sudden switch of direction, which then functions as a topic indicator (Type 12) to introduce the discussion about why the situation is different 'in this country.'

Global Functions: Theme and Plot

Although fragmentation often has a local rhetorical function, the fragments may also have global significance in a text. Example (19) facilitates the local flow of the argument but also highlights the key theme of the book, the failure of The Scheme in this particular country due to the greed of the participants.

In (20), the word 'unless' has thematic significance, since the story deals with the notion of coincidence. The fragment comes shortly after an explicit discussion of the meaning of the word 'unless' (Shields, 2003: 313) and also echoes the title of the book.

(20) By chance it was Friday, the day Tom drives by the corner of Bathurst and Bloor for a glimpse of her. She was not there. For the first time since April she was not there.
Unless, unless. He rang the bell at the hostel [. . .] (Shields, *Unless,* p. 314)

A similar fragment, with the single word 'Unless,' is repeated at the start of the following paragraph (2003: 314), and the fragment 'Unless we ask questions.' occurs in its own mini-paragraph two pages later (2003: 316). This type of heavy use of a fragment with explicit signaling of its importance can enable a fragment to play a global role in a novel.

Other examples of thematically important fragments are found in (1b) and (7), as already discussed. Example (4b) shows how under-specification can be used to stimulate suspense at a crucial point before a major plot revelation. See also Emmott *et al*. (2003) for examples of instances where fragmentation can be used to highlight key clues in detective fiction.

Rhythm and Iconicity

Fragments play a major role in providing rhythmic pacing in texts. In (21), a description of the labor pains as a woman gives birth, the Type 10 evaluative

fragments (including Type 2 echoing) provide a rhythmic alternation to the average length and longer sentences, which Barr (2001: 385) described as "toggling." The effect is also achieved by the silent stresses that are likely to occur before the fragments during reading.

(21) When the wave of pain had receded, and she lay spent, she was grimly flogging her mind to *imagine* the quality of the pain that had just gone. **Impossible**. [Then, when in pain, she tries to imagine no pain, but again fails.] With all her determination, she could not. There were two Marthas, and there was nothing to bridge them. **Failure**. **Complete failure**. (Lessing, *A Proper Marriage*, p. 164; Lessing's italics, our paraphrase in square brackets)

In (22), the lengthy first sentence is followed by a concluding fragment (Type 10) that rounds off this paragraph and gains its effect from the contrasting length and the silent stresses before the first 'Deadness' and before 'within.'

(22) The great, sun-dried dead church, the dead portales, the hopeless covered market-place, where, the first time she went, she saw a dead dog lying between the meat stalls and the vegetable array, stretched out as if for ever, nobody troubling to throw it away. **Deadness within deadness**. (Lawrence, "The woman who rode away," p. 39)

More specifically, fragmentation can often have iconic effects, where the rhythm may 'mime' specific types of action. Examples (14a) and (14b) 'mime' the speed and recurrence of actions respectively. Also, many of the examples shown earlier might be argued to be iconic insofar as they reflect the rhythms of speech and thought (or at least a conventional notion of the patterns of speech and thought in literary writing).

One problem for iconicity researchers is that the same type of writing style can have quite different meanings in context, even in the same literary work. In (23), the fragments mimic the speed of the focalizer hurtling through the city in an ambulance and also iconically reflect the 'shattering' of the city (actually the focalizer's perception of everything around her shattering in this moment of crisis). The representation of shattering is, however, specific to this context. Moreover, although fragments can often represent speed (as in [14a]), they can also represent slow movements, as in (24).

(23) The city shattered. Everything was in pieces. She knew it straight away, glimpsed it from the painful-white insides of the ambulance. **Frantic neon signs. Headlights chasing the dark. An office block, cracked with light. These shards of the broken city**. (Ali, *Brick Lane,* p. 117)

(24) She did not know what the words meant but the rhythm of them soothed her. Her breath came from down in her stomach. **In and out**. **Smooth**. **Silent**. Nazneen fell asleep on the sofa. (Ali, *Brick Lane*, p. 21)

Possibly, then, the interpretation owes more to the way the reader reads a series of fragments, as triggered by the scene being described.

Future Linguistic and Stylistic Research

There are several areas where further linguistic and stylistic study is needed of fragmentation:

Fragmentation in Different Types of Text

The examples in this article are drawn mainly from literary narratives. More work is needed to show the rhetorical functions of fragmentation in other types of texts, such as expository texts, newspapers, and advertisements. The extent to which the acceptability of fragments in writing differs crosslinguistically and diachronically also merits further investigation (for crosslinguistic and historical examples from written text, see Miller and Weinert, 1998: 41–45). It would also be interesting to study how fragmentation in written text differs from that in speech, since the former is not prompted by spontaneity (except, perhaps, the simulation of spontaneity in speech and thought representation).

Even in relation to literary texts, the study needs to be extended to cover different types of texts (e.g., drama and poetry). The list of fragment types shown earlier is not fully comprehensive; it could be developed further to describe the full range of examples that occur in narrative fiction. Special types of experimental writing may contain more dense fragmentation and may require a much broader range of categories.

Ellipsis and Fragmentation

Crystal and Davy's (1969) discussion of 'minor sentences' as being nonelliptical is useful for describing the fragments discussed in this article. In many cases, it would be difficult to construct a specific sentence around the fragment, and such reconstruction would destroy the rhythmic and rhetorical effects. Further research would be beneficial to show the dividing line or gradient between ellipsis and fragmentation.

Good and Bad Writing

As discussed earlier, novice writers have traditionally been warned against writing in incomplete sentences. Nevertheless, fragmentation is a very effective aspect of the style of some of our major literary writers.

More detailed study of fragmentation would be necessary to draw a distinction between the properties of ineffective and effective use of fragmentation, in order to make this type of stylistic analysis useful for pedagogical purposes.

Acknowledgments

This research was conducted as part of the LINCS Project (*Literature, narrative and cognitive science*) and STACS Project (*Stylistics, text analysis and cognitive science*). It was funded by two Arts and Humanities Research Board/Council grants (Innovation Award B/IA/AN8799/APN13740 and Research Grant B/RG/AN8799/APN17330), in addition to British Academy grant 32623). Sentence Processing

An essential part of understanding a sentence is to construct the appropriate syntactic structure. Research investigating how language users do this is usually referred to as sentence processing research. Most sentence processing research has focused on syntactic ambiguities. Although language users are often unaware of syntactic ambiguities, they are in fact very common, so an important goal of this research is to develop theories that explain how language users process them. Furthermore, syntactic ambiguities present a precious opportunity to gain insight into the architecture and mechanisms of the sentence processor. People often experience difficulty in adopting the intended analysis of syntactically ambiguous sentences and by examining when processing difficulty occurs, psycholinguists can study the workings of the sentence processor.

Sentence Processing Theories: Two-Stage Versus Constraint-Based Theories

The literature on syntactic ambiguity resolution is dominated by two largely incompatible classes of theories, two-stage and constraint-based theories. Two-stage theories claim that the processor initially draws upon a restricted range of information to construct a single analysis of an ambiguous structure. According to the most influential two-stage account, the garden-path theory, the syntactic processor is modular (e.g., Frazier, 1979, 1987; Rayner *et al.*, 1983). It claims that the processor initially adopts the analysis that is simplest in terms of syntactic tree structure (e.g., the fewest nodes), whereas other potentially useful information for resolving syntactic ambiguities is delayed until the second stage of processing. Other two-stage theories assume that the processor uses thematic role information during its initial stage (e.g., Pritchett, 1992). However, all two-stage theories claim that reanalysis occurs when the initial analysis is inconsistent with information that is used during the second stage of processing. Discovery of the misanalysis and subsequent reanalysis result in processing difficulty.

In contrast, constraint-based theories claim that all sources of information, including nonsyntactic constraints, immediately affect syntactic ambiguity resolution (e.g., MacDonald *et al.*, 1994; Trueswell *et al.*, 1993, 1994). They claim that the processor activates multiple analyses of a syntactic ambiguity in parallel. All sources of information have an immediate effect on their activation and the activation of an analysis is determined by the number and strength

An essential part of understanding a sentence is to construct the appropriate syntactic structure. Research investigating how language users do this is usually referred to as sentence processing research. Most sentence processing research has focused on syntactic ambiguities. Although language users are often unaware of syntactic ambiguities, they are in fact very common, so an important goal of this research is to develop theories that explain how language users process them. Furthermore, syntactic ambiguities present a precious opportunity to gain insight into the architecture and mechanisms of the sentence processor. People often experience difficulty in adopting the intended analysis of syntactically ambiguous sentences and by examining when processing difficulty occurs, psycholinguists can study the workings of the sentence processor.

Sentence Processing Theories: Two-Stage Versus Constraint-Based Theories

The literature on syntactic ambiguity resolution is dominated by two largely incompatible classes of theories, two-stage and constraint-based theories. Two-stage theories claim that the processor initially draws upon a restricted range of information to construct a single analysis of an ambiguous structure. According to the most influential two-stage account, the garden-path theory, the syntactic processor is modular (e.g., Frazier, 1979, 1987; Rayner *et al.*, 1983). It claims that the processor initially adopts the analysis that is simplest in terms of syntactic tree structure (e.g., the fewest nodes), whereas other potentially useful information for resolving syntactic ambiguities is delayed until the second stage of processing. Other two-stage theories assume that the processor uses thematic role information during its initial stage (e.g., Pritchett, 1992). However, all two-stage theories claim that reanalysis occurs when the initial analysis is inconsistent with information that is used during the second stage of processing. Discovery of the misanalysis and subsequent reanalysis result in processing difficulty.

In contrast, constraint-based theories claim that all sources of information, including nonsyntactic constraints, immediately affect syntactic ambiguity resolution (e.g., MacDonald *et al.*, 1994; Trueswell *et al.*, 1993, 1994). They claim that the processor activates multiple analyses of a syntactic ambiguity in parallel. All sources of information have an immediate effect on their activation and the activation of an analysis is determined by the number and strength

of the constraints supporting it. When the activation of one analysis is much higher than that of the alternative analyses, processing the ambiguity is easy. But when two analyses are approximately equally activated, they compete, and processing difficulty occurs.

The Use of Nonsyntactic Information

A large body of research has tested the two opposing classes of theories by investigating whether the use of nonsyntactic information is delayed relative to syntactic information. Ferreira and Clifton (1986) investigated sentences such as (1–4) in a reading experiment.

(1) The defendant examined by the lawyer turned out to be unreliable.
(2) The defendant that was examined by the lawyer turned out to be unreliable.
(3) The evidence examined by the lawyer turned out to be unreliable.
(4) The evidence that was examined by the lawyer turned out to be unreliable.

Sentence (1) contains a reduced relative clause (*examined by the lawyer*) that results in a temporary ambiguity, because the initial words also permit a main clause analysis (as in *the defendant examined the lawyer*). According to the garden-path theory, the processor initially adopts the main clause analysis, because it is structurally simplest. This correctly accounts for Ferreira and Clifton's (1986) finding that the disambiguating phrase (*by the lawyer*) in (1) is harder to read than in an unambiguous sentence like (2).

More interestingly, Ferreira and Clifton (1986) observed that readers experienced difficulty with reduced relatives even in (3), where the main clause analysis is ruled out by plausibility (evidence does not normally examine anything). This suggests that the processor bases its initial analysis on syntactic information and that the use of plausibility information is delayed, as claimed by the garden-path theory. However, Trueswell *et al.* (1994) argued that the plausibility manipulation in Ferreira and Clifton's study was too weak. With stronger materials, they showed that no difficulty occurred in (3) relative to (4). They argued that this supports constraint-based theories.

Other studies have investigated the use of contextual information. Constraint-based theories incorporate ideas from referential theory (Altmann and Steedman, 1988; Crain and Steedman, 1985), which claims that the processor favors the analysis with the fewest unsupported discourse presuppositions. In (5), the temporarily ambiguous PP *with the new lock* modifies the NP *the safe*.

(5) The burglar blew open the safe with the new lock.

This interpretation presupposes that there is more than one safe in the discourse, but only one has a new lock. However, in the absence of a context mentioning more than one safe, this presupposition is unsupported. Hence, (5) should be harder to process than the verb modifier interpretation in (6), which does not contain this presupposition.

(6) The burglar blew open the safe with the dynamite.

However, in a context mentioning more than one safe, as in (7), the NP modifier interpretation should be preferred.

(7) The burglar saw a safe with a new lock and a safe with an old lock.
He blew open the safe with the new lock.

The presupposition associated with the NP modifier is now supported, because the PP singles out one of the safes. In contrast, the verb modifier interpretation is infelicitous because it presupposes that the discourse contains only a single safe.

Several reading studies have shown that referential context affects syntactic ambiguity resolution (e.g., Altmann and Steedman, 1988); however, the effects are less strong than claimed by referential theory: in syntactic ambiguities with a strong bias for one analysis (in the absence of a context), discourse context does not appear to override structural preferences (e.g., Britt, 1994). This fits well with constraint-based theories. They claim that discourse information has a strong effect when other constraints do not strongly favor a single analysis. But when other constraints strongly favor one analysis, these constraints may override context effects.

Another important nonsyntactic constraint is the frequency with which structures occur in a language. Trueswell *et al.* (1993) investigated temporarily ambiguous sentences such as (8, 9).

(8) The student forgot the solution was in the book.
(9) The student hoped the solution was in the book.

Verbs such as *forget* occur more frequently with a direct object (as in *The student forgot the solution*) than with a sentence complement (as in [8]), whereas verbs such as *hope* show the opposite pattern. Trueswell *et al.* showed that the disambiguating region in (8) (*was in the*) took longer to read than in unambiguous sentences containing *that* following the critical verb. However, no difference was observed between (9) and

its unambiguous control, suggesting that frequency information had an immediate effect on syntactic ambiguity resolution. They concluded that this supports constraint-based theories.

Ongoing Controversies

The garden-path model may be able to account for early effects of nonsyntactic information by stipulating that such information is used so rapidly that its delay is undetectable (Ferreira and Clifton, 1989), but this makes its predictions rather unclear. As a result, constraint-based theories have become the dominant approach in the sentence processing literature. However, not all studies support the constraint-based view. Binder *et al.* (2001) investigated whether nonsyntactic information (plausibility and context) could make the main clause analysis in reduced relative/main clause ambiguities the preferred analysis, as predicted by constraint-based theories, but it did not. Clifton *et al.* (2003) investigated the use of plausibility information in reduced relative structures, but used a larger set of materials than Trueswell *et al.* (1994). They observed that plausibility information facilitated the reduced relative analysis, but it did not completely eliminate difficulty. Finally, some studies show that verb frequency information does not always eliminate processing difficulty (e.g., Pickering *et al.*, 2000).

Constraint-based theorists argue that such results do not provide evidence against constraint-based theories. Syntactic preferences may be particularly strong and therefore nonsyntactic information cannot always override them. Unfortunately, such claims make it difficult to derive exact and testable predictions as to how linguistic factors interact. In order to make constraint-based models more explicit and testable, researchers have started to build computational models (e.g., McRae *et al.*, 1998; Tabor and Tanenhaus, 1999). Furthermore, constraint-based theorists have argued that people's completions of sentence fragments provide a good estimate of usage frequencies, and therefore they can be used to predict parsing preferences (e.g., McRae *et al.*, 1998; Garnsey *et al.*, 1997). However, it is unclear whether parsing preferences are the result of usage frequencies or whether the same underlying factors influence both parsing preferences and usage frequencies. Hence, a promising alternative approach is to explain both parsing and production preferences as the result of semantic factors (e.g., McKoon and Ratcliff, 2003).

New Directions

Recent studies have started to address new issues. An important line of research explores the interactions between visual context and sentence processing by measuring people's eye movements to visual scenes while they listen to sentences. Tanenhaus *et al.* (1995) and Spivey *et al.* (2002) asked people to follow auditory instructions such as (10, 11).

(10) Put the apple on the towel in the box.
(11) Put the apple that's on the towel in the box.

They were presented with either a one-referent scene containing a single apple on a towel, or a two-referent scene containing two apples, one of which was on a towel. Both scenes also contained an empty towel without an apple, and a box. When people heard (10) while looking at the one-referent scene, they looked more often at the empty towel than when hearing (11). This indicates that they initially misinterpreted *on the towel* in the temporarily ambiguous sentence (10) as modifying the verb *put* and took it as the destination for the apple. However, for the two-referent scene, no such difference was observed, suggesting that the visual context immediately affected syntactic ambiguity resolution. Recent research has also used this visual-world method to investigate how children process syntactic ambiguities. Trueswell *et al.* (1999) showed that, in contrast to adults, children do not use the visual context. However, both adults and children appear to use verb frequency information (Snedeker and Trueswell, 2004).

Using a similar method, Altmann and Kamide, (1999; Kamide *et al.*, 2003) showed that listeners looked at edible objects when hearing sentences such as (12), even before they heard *cake*.

(12) The boy will eat the cake.

Kamide *et al.* (2003) argued that the processor anticipates properties of upcoming phrases, using both semantic and syntactic information up to that point. What properties it anticipates is less clear, in particular whether it anticipates syntactic structures. Furthermore, it is likely that the anticipations are at least partly triggered by the visual context. During normal language comprehension, such a context is usually absent, and people may therefore not make the same type of anticipations. Nevertheless, what these studies show is that in a visual context, sentence processing proceeds very rapidly and is highly incremental.

Other recent research has continued to use reading methods, but has addressed new questions. Van Gompel *et al.* (2005) investigated whether processing difficulty is the result of competition between analyses. Most constraint-based theories claim that competition should occur in globally ambiguous sentences with no strong bias for either analysis, because constraints support two analyses to an equal

extent. Hence, such sentences should be harder to process than disambiguated sentences, where only a single analysis is supported. However, Van Gompel *et al*. observed exactly the opposite pattern of results, suggesting that competition is not the mechanism causing processing difficulty. They argued that processing difficulty is due to reanalysis: globally ambiguous sentences are easy to process, because the initial analysis remains possible throughout the sentence, regardless of which analysis is adopted. In contrast, when a sentence is disambiguated, the initial analysis may be incorrect, and the processor has to reanalyze.

Christianson *et al*. (2001) showed that readers often fail to adopt the intended analysis in temporarily ambiguous sentences. In line with this, Ferreira (2003) argued that readers often construct shallow representations of the sentence, even for completely unambiguous sentences such as passives. Finally, researchers have started to show a renewed interest in how working memory constraints affect the processing of both ambiguous and unambiguous sentences (e.g., Caplan and Waters, 1999; Gibson, 1998; Gordon *et al*., 2004). Future research will probably continue to explore these and other new issues.

Serbia and Montenegro: Language Situation

B Arsenijevic, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

'Serbia and Montenegro' became the official name of the country as of February 4, 2003, as a result of the process of restructuring the country formerly known as 'The Federal Republic of Yugoslavia.' Serbia and Montenegro is the largest descendant of the former Socialistic Federative Republic of Yugoslavia and consists of two republics: Serbia and Montenegro. Within Serbia, there are two autonomous provinces, Vojvodina and Kosovo. Kosovo has been under the protectorate of the United Nations since 1999.

Language politics and manipulations of the history, official status and names of different languages played an important role in the numerous ethnical conflicts that took place from 1990 to 1999 and it is still a very sensitive issue in the whole area of the Balkans.

The official language of the Republic of Serbia is Serbian (with over 6 620 000 speakers in the territory of Serbia without Kosovo, or 88% of the population); an equal legal status is afforded to both the Cyrillic and the Roman alphabet, although the former is favored for Serbian state administration. Minority languages, which are also in official use in the regions where they are spoken, are Hungarian (according to the 2002 census data of the Statistical Institute of the Republic of Serbia, estimated at 286 500 speakers), Bosnian (134 500 speakers), Romany (82 000 speakers), Albanian (63 500 speakers), Slovakian (57 500 speakers), Valachian (55 000 speakers), Romanian (34 500 speakers), Croatian (27 500 speakers), Bulgarian (16 500 speakers), and Macedonian (14 500 speakers). Minority languages are used at all levels of education: in primary schools, high schools, and at colleges and universities.

One linguistic consequence of the political and ethnic processes of the 1990s is that the language that used to be officially called 'Serbo-Croat' has received several new ethnically and politically based names. Thus, the names 'Serbian,' 'Croatian,' and 'Bosnian' are politically determined and refer to the same language with possible slight variations. The language has two major dialects, Ekavian and Ijekavian. Although, in general, Ekavian is spoken more in Serbia (and parts of Croatia), and Ijekavian is spoken more in Montenegro (and also in Bosnia, Herzegovina, and parts of Croatia), these dialects do not coincide with the ethnically motivated names.

The language situation in Kosovo is less clear at present, because about 300 000 refugees from this province, mostly Serbs, are still in the process of returning to their homes. This fact makes the numbers of speakers reported unreliable. Today, according to the Statistical Office of Kosovo, about 1 672 000, or 88% of the inhabitants of Kosovo, speak Albanian, and about 133 000, or 7%, are speakers of Serbian. The rest of the population (5%) speaks mostly Romany, Bosnian, and Turkish.

The official language of the Republic of Montenegro is Serbian, but there are recent tendencies to introduce the name 'Montenegrin,' either parallel to or instead of the name 'Serbian.' Just as with Serbian, Croatian, and Bosnian, this term refers to the same language that used to be called Serbo-Croat, and is rather a matter of political decisions and convictions. The Cyrillic and the Roman alphabet are officially in use. The 2003 census data from the Statistical

Serbia and Montenegro: Language Situation

B Arsenijevic, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

'Serbia and Montenegro' became the official name of the country as of February 4, 2003, as a result of the process of restructuring the country formerly known as 'The Federal Republic of Yugoslavia.' Serbia and Montenegro is the largest descendant of the former Socialistic Federative Republic of Yugoslavia and consists of two republics: Serbia and Montenegro. Within Serbia, there are two autonomous provinces, Vojvodina and Kosovo. Kosovo has been under the protectorate of the United Nations since 1999.

Language politics and manipulations of the history, official status and names of different languages played an important role in the numerous ethnical conflicts that took place from 1990 to 1999 and it is still a very sensitive issue in the whole area of the Balkans.

The official language of the Republic of Serbia is Serbian (with over 6 620 000 speakers in the territory of Serbia without Kosovo, or 88% of the population); an equal legal status is afforded to both the Cyrillic and the Roman alphabet, although the former is favored for Serbian state administration. Minority languages, which are also in official use in the regions where they are spoken, are Hungarian (according to the 2002 census data of the Statistical Institute of the Republic of Serbia, estimated at 286 500 speakers), Bosnian (134 500 speakers), Romany (82 000 speakers), Albanian (63 500 speakers), Slovakian (57 500 speakers), Valachian (55 000 speakers), Romanian (34 500 speakers), Croatian (27 500 speakers), Bulgarian (16 500 speakers), and Macedonian (14 500 speakers). Minority languages are used at all levels of education: in primary schools, high schools, and at colleges and universities.

One linguistic consequence of the political and ethnic processes of the 1990s is that the language that used to be officially called 'Serbo-Croat' has received several new ethnically and politically based names. Thus, the names 'Serbian,' 'Croatian,' and 'Bosnian' are politically determined and refer to the same language with possible slight variations. The language has two major dialects, Ekavian and Ijekavian. Although, in general, Ekavian is spoken more in Serbia (and parts of Croatia), and Ijekavian is spoken more in Montenegro (and also in Bosnia, Herzegovina, and parts of Croatia), these dialects do not coincide with the ethnically motivated names.

The language situation in Kosovo is less clear at present, because about 300 000 refugees from this province, mostly Serbs, are still in the process of returning to their homes. This fact makes the numbers of speakers reported unreliable. Today, according to the Statistical Office of Kosovo, about 1 672 000, or 88% of the inhabitants of Kosovo, speak Albanian, and about 133 000, or 7%, are speakers of Serbian. The rest of the population (5%) speaks mostly Romany, Bosnian, and Turkish.

The official language of the Republic of Montenegro is Serbian, but there are recent tendencies to introduce the name 'Montenegrin,' either parallel to or instead of the name 'Serbian.' Just as with Serbian, Croatian, and Bosnian, this term refers to the same language that used to be called Serbo-Croat, and is rather a matter of political decisions and convictions. The Cyrillic and the Roman alphabet are officially in use. The 2003 census data from the Statistical

Institute of the Republic of Montenegro show that about 401 500, or 60% of the inhabitants of Montenegro, declare themselves as speakers of Serbian, about 145 000 (22%) speak Montenegrin, nearly 49 500 (7%) speak Albanian, 29 000 (4%) are speakers of Bosnian, and about 3000 speak either Croatian or Romany.

Serbian Lexicography

D Šipka, Arizona State University, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Sociopolitical circumstances in the region have shaped three distinct phases of Serbian lexicography (Early Serbian, Serbo-Croatian, and Modern Serbian).

Although some earlier glosses have been found, it is Serbian migrations to southern Hungary that gave rise to a series of early Serbian bilingual dictionaries, including Latin, German, Greek, and Turkish editions, stretching from the late 18th to the mid-19th century. These dictionaries were intended primarily to meet the daily needs of those learning foreign languages in this cultural environment. One of the most popular dictionaries from this series was the anonymous *Rečnik malij*, a German-Serbian subject matter dictionary with 37 lexical fields. This branch is somewhat of a side track primarily because its linguistic substance is a mixture of the Serbian and Russian redactions of Old Church Slavonic, quite distant from the *Što-dialect*, which served as the basis for the standard Serbian which emerged in the 19th century.

The Serbo-Croatian phase was initiated by the 1818 *Srpski rječnik* by Vuk Stefanović Karadžić, which was enlarged and corrected in 1852. These two editions promoted the *Što-dialect* common to Serbs and Croats, which after decades of polemics was finally accepted in the second half of the 19th century. In terms of its microstructure, this trilingual Serbian-Latin-German dictionary for the most part follows the tradition established by the earlier Croatian lexicography while having almost no connection with the Serbian tradition of that period.

The linguistic views of Vuk Karadžić and his followers molded the lexicographic treatment of the monumental Croatian 23-volume *Dictionary of the Croatian or Serbian Language*, compiled from 1880 to 1976. It is based on materials from the mid-19th

Sociopolitical circumstances in the region have shaped three distinct phases of Serbian lexicography (Early Serbian, Serbo-Croatian, and Modern Serbian).

Although some earlier glosses have been found, it is Serbian migrations to southern Hungary that gave rise to a series of early Serbian bilingual dictionaries, including Latin, German, Greek, and Turkish editions, stretching from the late 18th to the mid-19th century. These dictionaries were intended primarily to meet the daily needs of those learning foreign languages in this cultural environment. One of the most popular dictionaries from this series was the anonymous *Rečnik malij*, a German-Serbian subject matter dictionary with 37 lexical fields. This branch is somewhat of a side track primarily because its linguistic substance is a mixture of the Serbian and Russian redactions of Old Church Slavonic, quite distant from the *Što-dialect*, which served as the basis for the standard Serbian which emerged in the 19th century.

The Serbo-Croatian phase was initiated by the 1818 *Srpski rječnik* by Vuk Stefanović Karadžić, which was enlarged and corrected in 1852. These two editions promoted the *Što-dialect* common to Serbs and Croats, which after decades of polemics was finally accepted in the second half of the 19th century. In terms of its microstructure, this trilingual Serbian-Latin-German dictionary for the most part follows the tradition established by the earlier Croatian lexicography while having almost no connection with the Serbian tradition of that period.

The linguistic views of Vuk Karadžić and his followers molded the lexicographic treatment of the monumental Croatian 23-volume *Dictionary of the Croatian or Serbian Language*, compiled from 1880 to 1976. It is based on materials from the mid-19th

century and earlier. The subsequent *Dictionary of Serbo-Croatian standard and colloquial language*, published by the Serbian Academy of Arts and Sciences beginning in 1959, is now in 15 volumes with over 20 yet to be published. It is meant to be a continuation of the aforementioned Croatian dictionary project with corpora from the mid-19th century and, when finished, will have approximately 400 000 entries. Another sizable dictionary of the Serbo-Croatian phase is the six-volume standard language dictionary published between 1967 and 1976, initially jointly by Matica Srpska and Matica Hrvatska (the first two volumes) and by Matica Srpska alone thereafter. This dictionary was an object of heated political debate between Serbian and Croatian linguists.

The Serbo-Croatian phase has brought forth numerous other dictionaries which vary considerably in quality and importance. During this phase Serbian lexicography abandoned the Romanticist discursiveness of lexicographic entry (e.g., the presence of folktales within dictionary entries) and moved toward a structured and concise lexicographic treatment. The vast breadth of quality is particularly observable with bilingual dictionaries. The Serbo-Croatian phase ended with the disintegration of the former Yugoslavia in the early 1990s.

The principal projects of the Modern Serbian phase are still in progress, comprising an etymological dictionary, a dictionary of foreign words, a dictionary of synonyms, and continued work on the aforementioned dictionary by the Serbian Academy of Arts and Sciences. The most conspicuous gap in Serbian lexicography remains the absence of a modern one-volume monolingual dictionary.

Serbian-Croatian-Bosnian Linguistic Complex

E C Hawkesworth, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Bosnian

The official name of the language spoken in Bosnia Herzegovina is Bosnian. The status of the language in reality, however, is more complex, as may be seen in the language law adopted in 1993: "In the Republic of Bosnia and Herzegovina, the Ijekavian standard literary language of the three constitutive nations is officially used, designated by one of the terms: Bosnian, Serbian, Croatian. Both alphabets, Latin and Cyrillic, are equal." The law reflects the fact that the territory is inhabited by three national groups: Bosniaks (South Slav Muslims, the majority population of the Bosnian/Croatian Federation), Croats (Catholics, the majority population of the territory of Herzegovina, the southwestern area of the Bosnian/Croatian Federation); and Serbs (Orthodox, the majority population of the other Bosnian entity, known as *Republika srpska*). In practice, it is normally only Bosniaks (and those committed to the survival of Bosnia Herzegovina as a unified country), who refer to their language as 'Bosnian.' And it is logical enough that Croats should speak Croatian and Serbs Serbian now that there is no longer an all-inclusive Serbo-Croatian umbrella. The debate as to whether or not a distinct Bosnian language exists continues. At the time of writing, the standard language used by the official authorities in Sarajevo and other parts of the Federation may be described as distinct from the standard languages in Serbia and Croatia, but the process of standardization, through dictionaries, grammars, and scholarly studies, has yet to be completed. For the time being, it cannot be said that Bosnian has quite the same status as Croatian in terms of its recognition as a specific standard.

Croatian

Croatian is the official name of the language spoken in the territory of Croatia. To a considerable extent, the political tensions that ultimately led to the collapse of Yugoslavia were first reflected in issues related to language. Long before it was possible for ideas of political separation to be contemplated, in 1967, Croatian linguists published a Declaration on the Name and Position of the Croatian Literary Language, calling for official recognition of Croatian as a separate language. From the outset, however, it was clear that the Declaration had more to do with cultural and sociopolitical aspirations than linguistics. From 1971, nationalist policies in Croatian became steadily more entrenched, leading eventually to the secession of Croatia (and Slovenia) from the common state of Yugoslavia in 1992. As language and statehood have been inextricably linked since the rise of nation states in Europe, it was understandable that nationalist politics should place particular emphasis on separating the Croatian element of the Serbo-Croatian language as far as possible from its Serbian counterpart. To this end, archaic words were reintroduced, neologisms forged and various 'differential' dictionaries published in an effort to raise the consciousness of individual Croats to the special nature of their language and to purify the Croatian language of Serbianisms. Apart from lexical items and favoring two characteristic syntactic differences (the infinitive in Croatian for dependent verbs, as opposed to *da* + present tense in Serbian; verb + interrogative particle *li* for questions as opposed to *da li* + verb in Serbian), particular emphasis has been placed on differences in word formation. At the height of the nationalist era, in the extreme circumstances of war and later, as Croatia consolidated its position as an independent state, linguists were particularly active. Some of the results of this frenzy were inevitably artificial and at times entertaining. This phase of heightened self-consciousness has now passed, with the recognition that Croatian has been widely accepted as a separate standard at an official level. Speakers may now be left to express themselves naturally and the language to develop in a more organic manner.

Serbian

Serbian is the official name of the language spoken in the territory of Serbia and Montenegro. Unlike the

For the time being, it cannot be said that Bosnian has quite the same status as Croatian in terms of its recognition as a specific standard.

Croatian

Croatian is the official name of the language spoken in the territory of Croatia. To a considerable extent, the political tensions that ultimately led to the collapse of Yugoslavia were first reflected in issues related to language. Long before it was possible for ideas of political separation to be contemplated, in 1967, Croatian linguists published a Declaration on the Name and Position of the Croatian Literary Language, calling for official recognition of Croatian as a separate language. From the outset, however, it was clear that the Declaration had more to do with cultural and sociopolitical aspirations than linguistics. From 1971, nationalist policies in Croatian became steadily more entrenched, leading eventually to the secession of Croatia (and Slovenia) from the common state of Yugoslavia in 1992. As language and statehood have been inextricably linked since the rise of nation states in Europe, it was understandable that nationalist politics should place particular emphasis on separating the Croatian element of the Serbo-Croatian language as far as possible from its Serbian counterpart. To this end, archaic words were reintroduced, neologisms forged and various 'differential' dictionaries published in an effort to raise the consciousness of individual Croats to the special nature of their language and to purify the Croatian language of Serbianisms. Apart from lexical items and favoring two characteristic syntactic differences (the infinitive in Croatian for dependent verbs, as opposed to *da* + present tense in Serbian; verb + interrogative particle *li* for questions as opposed to *da li* + verb in Serbian), particular emphasis has been placed on differences in word formation. At the height of the nationalist era, in the extreme circumstances of war and later, as Croatia consolidated its position as an independent state, linguists were particularly active. Some of the results of this frenzy were inevitably artificial and at times entertaining. This phase of heightened self-consciousness has now passed, with the recognition that Croatian has been widely accepted as a separate standard at an official level. Speakers may now be left to express themselves naturally and the language to develop in a more organic manner.

Serbian

Serbian is the official name of the language spoken in the territory of Serbia and Montenegro. Unlike the

other components of the Serbian-Croatian-Bosnian linguistic complex, Serbian, as the standard language of the Serbs and Montenegrins, has not changed essentially from its earlier incarnation as Serbo-Croat. It was the Croats who opted to remove their language from the dual name, and set about making their standard as distinct as possible from standard Serbian (see 'Croatian'), while the Serbs had only to stand still. The process of the disintegration of standard Serbo-Croatian may thus be described as 'assymetrical and asynchronic' (Ljubomir Popovic, 'From Serbian to Serbo-Croatian to Serbian,' in Bugarski and Hawkesworth, 2004). In response, a Serbian Language Standardization Committee was set up to describe the current situation and Serbian has now been officially recognized as a separate language within Slavonic studies.

Serbian-Croatian-Bosnian Linguistic Complex

The language formerly known as Serbo-Croat belongs, with Bulgarian, Slovene, and Macedonian, to the South Slav branch of the Slavonic language family. The first written records are 11th-century inscriptions in stone in both the Glagolitic and related Cyrillic scripts. The cultural division between the two variants reflects their history: the western Latin-script culture of Croatia, in the orbit of the Catholic Church and later the Hapsburg Monarchy; and the eastern, Cyrillic, Byzantine, Orthodox culture of Serbia.

The dia-system linguistic complex is the most heterogeneous Slavonic dia-system, with an exceptionally large variety of dialects, some with six or seven cases, some with four, and a great variety of verbal tenses. At the same time, these dialects have a striking degree of connectedness, containing characteristic features, which distinguish the complex from all other Slavonic languages. One of these is its archaic prosodic system, in which stress position, vocalic quantity (length/shortness) and tone (rising/falling) are marked. The traditional accents are long falling: *noć*; short falling: *kuća*; long rising: *réka*; short rising: *ostati*. There are not many minimal pairs. Examples would be *grad* 'hail' and *grad* 'town'; *pas* 'dog' and *pas* 'belt, waist; pass'; and the sentence *Sam sam* 'I [masc.] am alone'.

In terms of morphology, the structure has remained complex, although one feature of Old Slavonic – the dual – has disappeared from the declensions and conjugations of all dialects in the complex. Case and verbal endings and accent shifts are the main morphological categories.

Word order is free, with the exception of strict rules governing the position of enclitics. These are verbal and pronominal short forms and the interrogative and reflexive particles.

Orthography has experienced the systematization of the Serbo-Croatian vernacular, which was carried out in the mid-19th century on phonetic principles, with one letter corresponding to one sound, making its orthography one of the most consistent in Europe. There is exact correspondence between the two scripts so that transliteration from one to the other is straightforward. There are three symbols unique to the language: **ć, ħ; đ ђ; dž џ.** For example:

Ijekavian variant (characterized by the rendering of Old Slavonic *jat* as *je* or *ije*, and spoken in Croatia, Bosnia, and Montenegro):
Od dviju sjevernih skupina, tj. istoćne i zapadne, juæna se razlikuje nizom osobina.
Ekavian variant (characterized by the rendering of Old Slavonic *jat* as *e*, and spoken in most of Serbia, which can equally well be written in the Latin script):
Од двеју северних скупина, тј. источне и западне, јужна се разликује низом особина.
'The Southern (Slavonic) group is distinguished from the two Northern groups, i.e., the Eastern and Western, by a series of features.'

Extensive bibliographies, as well as detailed studies, on the language situation of former Yugoslavia may be found in Bugarski *et al.*, 1992; the current situation is covered in the sequel: *Language in the former Yugoslav lands,* Slavica, 2004.

Serbo-Croat

The linguistic unity of the majority of the Southern Slav population of the Hapsburg and Ottoman lands that were to become Yugoslavia after the collapse of these empires in the First World War was first acknowledged in the joint Literary Agreement of 1850. The name 'Serbo-Croat' was officially adopted with the formation of the Kingdom of the Serbs, Croats, and Slovenes (known as Yugoslavia from 1928). It was never a straightforward phenomenon, however, as can be seen in the description adopted by many scholars: a polycentric standard language. The language could be officially termed 'Serbo-Croat,' 'Croato-Serbian,' 'Serbian and Croatian,' 'Croatian and Serbian,' 'Serbian or Croatian,' 'Croatian or Serbian.' In practice, from the end of the 1960s, most people in Croatia and Serbia referred to their language as 'Croatian' or 'Serbian,' respectively, simply for convenience, without this label implying any separatist tendencies. This situation lasted until the collapse of Yugoslavia in the wars of 1991–1995. Since the establishment of the independent states of Bosnia Herzegovina, Croatia, and Serbia and

Montenegro (still officially known as Yugoslavia until 2003), the term 'Serbo-Croat' no longer has any official validity in sociopolitical terms. The language spoken in these countries is now officially known as Bosnian, Croatian, and Serbian, respectively. In linguistic terms, the standard language remains essentially the same, but the sociopolitical reality is that it no longer has a single name. When native speakers wish to refer to the language in its broader sense, beyond the borders of their own homeland, they tend to say 'naπ jezik' or 'naπki (our language). For the purposes of the War Crimes Tribunal in The Hague, it is known as BCS. University departments in Europe where it is taught refer to it variously as Bosnian/Croatian/Serbian (Austria, Norway); Serbo-Croatian (Denmark); Serbo-Croat (France); South Slavic (Finland); Serbian/Croatian/Bosnian (Sweden); Serbian and Croatian (UK). In the absence of an entirely satisfactory solution, in this volume the term 'Serbian-Croatian-Bosnian linguistic complex' has been adopted as a clumsy but accurate description.

Serial Verb Constructions

U Ansaldo, Universiteit van Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

A serial verb construction (SVC) can be formally described as a clause consisting of two or more predicates showing a number of properties that suggest treating them as one structural unit. Such a construction denotes a single, complex event; typically, the secondary predicate expresses an extension or an aspect of the basic predicate. There is, however, significant variability within structural realizations of SVCs, a fact that leads to difficulties in characterizing SVCs as a unitary phenomenon.

Grammar and Semantics

Formal Features

A working definition of SVCs can go as follows: "A serial verb construction contains two or more verb roots that are neither compounded (...) nor members of separate clauses. Serial verbs occur in all types of languages, but may be more common in languages that have little or no verbal morphology (...)" (Payne, 1997: 307). Although it is true that languages of the isolating type frequently employ serialization, a number of more recent studies have clearly shown that SVCs also occur in languages with rich morphological indexation. Serialization has in fact been abundantly reported on for languages of different structural types, from morphologically isolating, verb-medial languages (e.g., Sinitic languages and creoles) to morphologically complex, verb-final languages (e.g., Papuan). SVCs are a feature of West African languages (Bamgbose, 1974; Givón, 1975; Lord, 1989, 1993); creoles (Sebba, 1987; Muysken and Veenstra, 1995; Veenstra, 1996); Sinitic languages (Li and Thompson, 1981; Matthews and Yip, 1994); Southeast Asian languages such as Hmong-Mien, Tai-Kadai, and Mon-Khmer (Matisoff, 1969; Bisang, 1996); and Oceanic languages (Crowley, 2002). It is interesting to note that in at least three geographical areas SVCs

Montenegro (still officially known as Yugoslavia until 2003), the term 'Serbo-Croat' no longer has any official validity in sociopolitical terms. The language spoken in these countries is now officially known as Bosnian, Croatian, and Serbian, respectively. In linguistic terms, the standard language remains essentially the same, but the sociopolitical reality is that it no longer has a single name. When native speakers wish to refer to the language in its broader sense, beyond the borders of their own homeland, they tend to say 'naπ jezik' or 'naπki (our language). For the purposes of the War Crimes Tribunal in The Hague, it is known as BCS. University departments in Europe where it is taught refer to it variously as Bosnian/Croatian/Serbian (Austria, Norway); Serbo-Croatian (Denmark); Serbo-Croat (France); South Slavic (Finland); Serbian/Croatian/Bosnian (Sweden); Serbian and Croatian (UK). In the absence of an entirely satisfactory solution, in this volume the term 'Serbian-Croatian-Bosnian linguistic complex' has been adopted as a clumsy but accurate description.

Serial Verb Constructions

U Ansaldo, Universiteit van Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

A serial verb construction (SVC) can be formally described as a clause consisting of two or more predicates showing a number of properties that suggest treating them as one structural unit. Such a construction denotes a single, complex event; typically, the secondary predicate expresses an extension or an aspect of the basic predicate. There is, however, significant variability within structural realizations of SVCs, a fact that leads to difficulties in characterizing SVCs as a unitary phenomenon.

Grammar and Semantics

Formal Features

A working definition of SVCs can go as follows: "A serial verb construction contains two or more verb roots that are neither compounded (...) nor members of separate clauses. Serial verbs occur in all types of languages, but may be more common in languages that have little or no verbal morphology (...)" (Payne, 1997: 307). Although it is true that languages of the isolating type frequently employ serialization, a number of more recent studies have clearly shown that SVCs also occur in languages with rich morphological indexation. Serialization has in fact been abundantly reported on for languages of different structural types, from morphologically isolating, verb-medial languages (e.g., Sinitic languages and creoles) to morphologically complex, verb-final languages (e.g., Papuan). SVCs are a feature of West African languages (Bamgbose, 1974; Givón, 1975; Lord, 1989, 1993); creoles (Sebba, 1987; Muysken and Veenstra, 1995; Veenstra, 1996); Sinitic languages (Li and Thompson, 1981; Matthews and Yip, 1994); Southeast Asian languages such as Hmong-Mien, Tai-Kadai, and Mon-Khmer (Matisoff, 1969; Bisang, 1996); and Oceanic languages (Crowley, 2002). It is interesting to note that in at least three geographical areas SVCs

appear to be a strong areal feature: Southeast Asia, West Africa, and the Pacific/Papua New Guinea (Durie, 1995). There is also substantial evidence of SVCs in Central and South American languages (cf. Aikhenvald, 2003), some languages of Australia, and Korean.

Typical features of serialization include the following (cf. Givón, 1990; Durie, 1997; Payne, 1997):

1. The construction is interpreted as a single clause describing a complex event.
2. There is only one subject marked for the main predicate (but it may be marked on each verb separately).
3. There is no overt coordination/subordination within the construction.
4. One or more arguments of the clause are shared.
5. The construction is a single clause in which tense, modality, and aspect (TMA) and polarity markers are shared.
6. The construction is perceived as one intonational unit.
7. The construction may be lexicalized or grammaticalized.

It is important to note that these features represent a cluster of prototypical features in serializing languages; when we look at actual examples of SVCs, it is clear that not all conditions are met in all languages. The examples that follow are from languages of different morphological types in which SVCs are found. (The tones for Sinitic languages are shown in tone numbers for that language).

Example (1) is from American English (Payne, 1997: 307), a mildly agglutinative SVO language.

(1) run go get me a newspaper

Examples (2), Sranan (Sebba, 1987: 53); (3), Cantonese (Yue Chinese); and (4), Twi (Akan) (Lord, 1993: 143), are from isolating SVO languages.

(2) wan man go luku wan dansi
a man go look a dance
'a man went to watch a dance'

(3) ngo^{5} maai^{5} syu^{1} bei^{2} koei^{5}
1.SING buy book give 3.SING
'I buy her a book'

(4) me-wɔ sika me-seŋ no
I-have money I-SUR him
'I have more money than he has'

Examples (5), Akan (Schachter, 1974: 258), and (6), Papiamentu (Muysken and Veenstra, 1995: 289), are from inflectional SVO languages.

(5) mede aburow migu msum
take.1.SING corn flow.1.SING water.in
'I pour corn into the water'

(6) e-l a bula bai
3-SING ASP fly go
'he flew away'

Examples (7), Miskitu: Misumalpan (Mískito) (Hale, 1991: 10); (8), Tibetan (Delancey, 1990); and (9), Jabêm (Yabem) (Bisang, 1986: 146–147; my translation), are from inflectional SOV languages.

(7) witin sula yab-an plap-an
he deer cause-OBV.3 run-PAST.3
'he caused the deer to run'

(8) q^{h}ó p^{h}oo čĩ pɑ́ɑ̀
he.ABS escape went PERF.DISJUNCT
'he escaped away'

(9) ka-toc amê kê-kô màsac
3.SING-place yam 3.SING-stand floor
'I put the yams on the floor'

Example (10) is from Barai (Foley and Olson, 1985: 44), an isolating SOV language.

(10) fu burede ije sime abe ufu
he bread DEF knife take cut
'he cut the bread with the knife'

As is evident from these examples, departures from what is generally believed of serialization are found. For example, more than one verb in the construction can be inflected for person and number, in contrast to the specification in feature 5, as in examples (3) and (5). Also, there can be different subjects for an SVC, as in example (7), thereby contradicting feature 2; and, example (1) is dubious in the light of the same-event feature 1.

Functional Features

Although showing quite a diverse array of superficial structures, from a functional point of view, SVCs tend to show even more consistency. A functional typology of SVCs should include at least the following types:

1. Directional, expressing movement toward, movement away from, or presence at a given location, as in (1), (2), (6), (8).
2. Argument marking, such as transitive marking; comitative or instrumental, as in (10); benefactive, as in (3); causative, as in (7); or complementizer (cf. Lord, 1993).
3. TMA marking.
4. Comparative degree (surpass), and in (4).

The internal sequencing of SVCs yields yet another typology. Durie (1997) suggested that within one and the same language we may be able to distinguish different types of serialization based on two different parameters: the inflectional parameter and the symmetry parameter. The former is particularly useful for

capturing the difference between verb compounding and serialization, two strategies that tend to be in complementary distribution in languages. Durie proposed distinguishing four types of serialization as a result of the interaction of the following features: contiguous/noncontiguous and incorporating/nonincorporating. The latter relates to the nature of constituents within the SVC and yields three types of SVCs:

1. Symmetrical, in which the constituents are grammatical equals and appear in iconic order (i.e., according to the order of events).
2. Asymmetrical, in which the noncore verb functions as a semantic variation of the core verb and no iconic order can be found.
3. Ambient, a hybrid of (1) and (2).

Note that the relation between the serializing predicates may be relevant from a formal perspective because verb forms that specialize as adverbial subordination can be treated as converbs in the typological literature (cf. Haspelmath, 1995). In such cases, usually we refer to verbs that cannot occur as main verbs on their own. This is not always the case of the verbs in the previous examples because they often retain full or partial functional value (cf. Ansaldo, 1999). Bisang (1995) suggested treating these cases as serial units, that is, as verb serialization in a narrow sense, with the influence of grammaticalization and lexicalization, as opposed to verb serialization in a broader sense. Serial units would also include structures such as 'resultatives,' as in Mandarin (Mandarin Chinese):

(11) ta^{1} chi^{1} bao^{3} le
3.SING eat full ASP
'she/he ate his/her fill'

In these structures, typical of Sinitic languages and common to mainland Southeast Asia, the noncore verb expresses the **result** of an event (see example (3)).

Diachronic Aspects

A particularly interesting aspect of serialization is its link to grammaticalization, that is, to the process whereby lexical items fossilize within a construction and assume grammatical function. Within the verbal domain, an SVC provides an ideal ground for the noncore verbs to fossilize into a given function and eventually deverbalize, although they do not necessarily undergo a full semantic loss (cf. Matisoff, 1969; Bisang, 1991, 1996; Ansaldo, 1999). The items that grammaticalize are typically found within a heterogeneous pool of semantic concepts and lead to the emergence of a number of constructions, illustrated next with examples mostly from Sinitic and creole varieties (cf. Bruyn, 1996, on creolization and grammaticalization).

Aspect

- Completive. The grammaticalization of 'to finish' as the completive marker in Saramaccan (Bakker *et al.*, 1995: 257).

  (12) a nján di físi káá
  he eat the fish already
  'he already ate the fish'

  Here *káá* is etymologically derived from a verb (borrowed from Portuguese) meaning 'to finish'; from what used to be a SVC, it has grammaticalized into a completive construction.
- Nonpunctual (durative). The grammaticalization of 'to stand' as the durative or habitual marker in Fa d'Ambu (Bakker *et al.,* 1995: 251).

  (13) ineni xa tabaya
  they HAB work
  'I work/am working'

  Here *xa* is derived from a verb originally expressing location.
- Experiential, The grammaticalization of 'to pass/cross' to the experiential marker in Mandarin.

  (14) wo^{3} qu^{4} guo
  1.SING go EXP
  'I've been there (at least once)'

  In Sinitic languages, the marker guo/gwo can also function as a lexical item meaning 'to pass.' Furthermore, it also grammaticalizes into a surpass marker (cf. Ansaldo, 1999) in Cantonese and other Southern Sinitic varieties.

  (15) ngo^{5} faai^{3} gwo^{3} lei^{5}
  1.SING fast SUR 2.SING
  'I am faster than you'

Case

- Patient. The grammaticalization of 'to take/grab' to the patient marker in Mandarin.

  (16) ba^{3} nei^{4} ben^{3} shu^{1} gei$^{3>2}$ wo^{3}
  OBJ DET.NUM CL book give 1.SING
  'give me that book'

  Ba^{3}, originally 'to grasp,' has grammaticalized to a patient marker.
- Beneficiary. The grammaticalization of 'to give' as the beneficiary marker in Fa d'Ambu (Post, 1995: 201).

  (17) Malía ma dyana ba da pe-déli
  Maria take banana go give father
  'Maria brought a banana to her father'

- Instrumental or Comitative. The grammaticalization of 'to use' (but also 'to take') to the instrument (sometimes associative) marker in Papiamentu (Sebba, 1987: 171):

(18) e-l a tuma e kuchu korta e krani
3SG-PAST take the knife cut the meat
'he cut the meat with the knife'

- Locative. The grammaticalization of 'to be at' as the location marker in Mandarin.

(19) ta^1 zai^4 jia^1 kan^4 shu^1
3.SG at home look book
's/he reads at home'

Directional Markers

The grammaticalization of 'to come' in Mandarin.

(20) zuo^4 xia^4 lai^2 ba
sit down come PRT
'sit down!'

Grammaticalization

These grammaticalization paths are attested crosslinguistically in a vast number of languages. The semantic pool of concepts from which the lexical items are chosen is rather limited, and the crosslinguistic similarity can be so striking and cut through such different genetic groups that it suggests areal convergence, for example, in the case of Southeast Asia (cf. Matisoff, 1969; Bisang, 1996; Ansaldo, 1999), and/or universal grammaticalization tendencies.

Typological Challenges

It will be obvious from the examples that defining SVCs is a rather complex enterprise. A basic problem is establishing what exactly is being compared; as Sebba (1987: 1) pointed out, in many languages it is difficult to provide a satisfying definition of verb in the first place. Moreover, not all types of verbs in a series should be treated as SVCs; a distinction should be made between serialization and patterns of subordination, coordination, and so on. An additional problem is the plethora of terms that have been created in language-specific contexts to capture aspects of serialization, such as resultative verbs, directional verbs, locative copulas, verboids, and coverbs. Finally, certain criteria for deciding on the serial status of a construction should be treated carefully, for example, the 'tonal unit' criterion, which suggests that a SVC is realized as a single intonational unit (Lehmann, 1988); as noted in Crowley (2002), the risk of faulty subjective judgments should be weighed carefully in instances of this kind.

A conservative and cautious set of diagnostics for recognizing a 'true' SVC is put forward in Sebba (1987: 39); it requires, in short, that (1) both verbs be lexical (i.e., capable of independent function), (2) both verbs be assigned the same TMA categories, and (3) there be no clause boundary or conjunction between the verbs. Even this narrow set of properties encounters difficulties when tested on any specific language, and it may be the case that satisfying a definition of SVCs can be achieved only at the language-specific level. As suggested in Durie (1997), a phenomenon such as serialization is likely to evade syntactic theorizing and may be better understood as being based on culture-specific constructions of eventhood and fusion in complex argument structure (cf. Alsina *et al.*, 1997).

Setälä, E. N. (1864–1935)

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Setälä was the dominant Finnish linguist in the late 19th and first part of the 20th century. He began studying linguistics at school with the poet, linguist, and politician Arvid Genetz as one of his teachers. At the age of 16 (1880), Setälä published his legendary Finnish syntax, which for many decades was the standard textbook in the field. The book was, however, not very original but was largely based on material and analyses taken from another Finnish linguist (Adolf Waldemar Jahnsson; see Karlsson, 2000). During his long stays in Uppsala and Leipzig, Setälä got acquainted with leading linguists of the neogrammarian school and introduced the neogrammarian theory in Finland and in Finno-Ugric linguistics through two masterly studies: his dissertation from 1886 and a thesis produced for the competition

Setälä, E. N. (1864–1935)

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Setälä was the dominant Finnish linguist in the late 19th and first part of the 20th century. He began studying linguistics at school with the poet, linguist, and politician Arvid Genetz as one of his teachers. At the age of 16 (1880), Setälä published his legendary Finnish syntax, which for many decades was the standard textbook in the field. The book was, however, not very original but was largely based on material and analyses taken from another Finnish linguist (Adolf Waldemar Jahnsson; see Karlsson, 2000). During his long stays in Uppsala and Leipzig, Setälä got acquainted with leading linguists of the neogrammarian school and introduced the neogrammarian theory in Finland and in Finno-Ugric linguistics through two masterly studies: his dissertation from 1886 and a thesis produced for the competition

for the professorship in Helsinki (1890). In 1893 Setälä became professor of Finnish in Helsinki.

Setälä developed in opposition to his former teacher Genetz his own theory of the reconstructed phonological system of Proto–Finno–Ugric. Setälä dominated Finnish linguistics totally during his lifetime and established the neogrammarian paradigm and his own reconstruction of the protolanguage as a frame that no student and no Finnish linguist could go beyond without consequences. One effect of this authoritarian academic policy, which dominated Finnish linguistics for many years after Setälä's death, was that structuralism came later to Finland than to the other Nordic countries.

In 1896, Setälä proposed three great dictionary projects covering (a) Finnish dialects, (b) modern literary Finnish, and (c) old literary Finnish. These projects were in many respects problematic, not the least due to Setälä's mixing private and public means in the running of the projects. Furthermore, in a small country like Finland, three such big linguistic projects bound a considerable part of both human and personnel resources and left little to other linguistic activities.

In the last part of his life (i.e., after 1917), Setälä was very active in politics. He wrote the Finnish Declaration of Independence (1917) and was Minister of Education, Minister of Foreign Affairs, and Finnish ambassador to Copenhagen and Budapest.

Sexist Language

M Hellinger, Johann Wolfgang Goethe Universität, Frankfurt am Main, Germany

© 2006 Elsevier Ltd. All rights reserved.

Sexist Language

Sexist language can be defined as one type of discriminatory language (use); it refers to linguistic expressions that exclude, trivialize, or insult (mainly) women. Linguistic manifestations of such practices are female invisibility (*mankind*), asymmetrical gender-marking (*lady philosopher*), and stereotyping (*doctors and their wives*). For a documentation of sexist language practices in 30 languages of diverse origin, structure, and typological affiliation, see Hellinger and Bußmann (2001–2003). A major issue in ongoing debates about sexist language is whether it is a manifestation of conservative usage indicating how women (and men) are portrayed in a particular culture, or whether it is harmful in itself, contributing toward the maintenance of gender stereotypes. While the first view takes language as a symptom, the latter sees language as one cause of social inequality (Miller and Swift, 1995; Cameron, 1992: 102). Alternatives for discriminatory wording have been proposed by feminist linguistic activists as well as language planning agencies (Pauwels, 1998; 2003). Such initiatives for deliberate change have been interpreted as a challenge to the political and social status quo (Romaine, 1999: 293; Cameron, 1995).

Categories of Gender

In a theoretical framework capable of analyzing gender in a language, at least four categories of gender must be differentiated: grammatical, lexical, referential, and social.

Grammatical Gender

Grammatical gender is an inherent morphosyntactic property of the noun which controls agreement between the noun's gender class and some so-called satellite element which may be an article, adjective, pronoun, or verbal form. Satellite elements must be gender-variable, i.e., they must allow for a choice between at least two values, e.g., feminine and masculine (as in French and Italian), or feminine, masculine, and neuter (as in Russian and German). With few exceptions, each noun typically belongs to one gender class only, which is defined by an interaction

for the professorship in Helsinki (1890). In 1893 Setälä became professor of Finnish in Helsinki.

Setälä developed in opposition to his former teacher Genetz his own theory of the reconstructed phonological system of Proto–Finno–Ugric. Setälä dominated Finnish linguistics totally during his lifetime and established the neogrammarian paradigm and his own reconstruction of the protolanguage as a frame that no student and no Finnish linguist could go beyond without consequences. Sexist Language

Sexist language can be defined as one type of discriminatory language (use); it refers to linguistic expressions that exclude, trivialize, or insult (mainly) women. Linguistic manifestations of such practices are female invisibility (*mankind*), asymmetrical gender-marking (*lady philosopher*), and stereotyping (*doctors and their wives*). For a documentation of sexist language practices in 30 languages of diverse origin, structure, and typological affiliation, see Hellinger and Bußmann (2001–2003). A major issue in ongoing debates about sexist language is whether it is a manifestation of conservative usage indicating how women (and men) are portrayed in a particular culture, or whether it is harmful in itself, contributing toward the maintenance of gender stereotypes. While the first view takes language as a symptom, the latter sees language as one cause of social inequality (Miller and Swift, 1995; Cameron, 1992: 102). Alternatives for discriminatory wording have been proposed by feminist linguistic activists as well as language planning agencies (Pauwels, 1998; 2003). Such initiatives for deliberate change have been interpreted as a challenge to the political and social status quo (Romaine, 1999: 293; Cameron, 1995).

Categories of Gender

In a theoretical framework capable of analyzing gender in a language, at least four categories of gender must be differentiated: grammatical, lexical, referential, and social.

Grammatical Gender

Grammatical gender is an inherent morphosyntactic property of the noun which controls agreement between the noun's gender class and some so-called satellite element which may be an article, adjective, pronoun, or verbal form. Satellite elements must be gender-variable, i.e., they must allow for a choice between at least two values, e.g., feminine and masculine (as in French and Italian), or feminine, masculine, and neuter (as in Russian and German). With few exceptions, each noun typically belongs to one gender class only, which is defined by an interaction

of formal and semantic assignment rules (Corbett, 1991).

Languages with grammatical gender have developed language-specific rules of agreement. Thus, in the highly inflected Slavic languages, overt gender-marking is much more visible than in most Germanic languages, simply because more satellite elements have gender-variable forms. In the following example from Russian, agreement is established between the feminine noun *studentka* 'female student' and various verbal, pronominal, and adjectival forms (Doleschal and Schmid, 2001):

(1) *Prišl-a* *moj-a* *byvš-aja* *studentka,*
came-FEM my-FEM former-FEM student.FEM
kotor-aja *očen'* *umn-aja.* *On-a*
who-FEM very intelligent-FEM she-FEM
mogl-a *by* *pomoč'.*
might-FEM COND help
'A former student of mine, who is very intelligent, has come. She might help.'

Of course, this kind of formal agreement does not exist in grammatically genderless languages such as Turkish, Chinese, or English.

Lexical Gender

Lexical gender constitutes part of the semantics of animate/personal nouns. For example, in English, personal nouns such as *daughter* and *son* are lexically specified as [female] and [male], respectively. Such nouns may be classified as 'gender-specific,' in contrast to nouns such as *citizen* or *patient*, which are considered to be 'gender-neutral' or 'gender-indefinite.' Of course, languages have lexical gender nouns irrespective of whether they also possess grammatical gender. Lexical gender is an important parameter in the structure of kinship terminologies, address terms, and a number of basic, i.e., frequently used personal nouns such as *woman*, *man*, *girl*, and *boy*. The examples in (2) are from Spanish and Danish which have two grammatical gender classes each, i.e., feminine and masculine in Spanish, and common and neuter in Danish:

(2)	Female-specific	Male-specific	Gender-indefinite
Spanish	*hija* (f)* 'daughter'	*hijo* (m) 'son'	*individuo* (m) 'individual'
	hermana (f) 'sister'	*hermano* (m) 'brother'	*persona* (f) 'person'
	profesora (f) 'female professor'	*profesor* (m) 'male professor'	'professor'
Danish	*datter* (c) 'daughter'	*søn* (c) 'son'	*barn* (n) 'child'
	søster (c) 'sister'	*bror* (c) 'brother'	*menneske* (n) 'person'
	lærerinde (c) 'female teacher'	*lærer* (c) 'male teacher'	*lærer* (c) 'teacher'

* (f) = feminine, (m) = masculine, (n) = neuter, (c) = common gender.

Lexical gender may or may not be marked on the noun itself. In English, most human nouns are not formally marked for lexical gender, with exceptions such as *widow<u>er</u>* or *princ<u>ess</u>*, which show overt lexical gender-marking by suffixation. By contrast, lexical gender is marked extensively in German, because most personal feminines are derived from corresponding masculines by means of the fully productive suffix *-in*, as in *Bischöf<u>in</u>* 'female bishop,' *Soldat<u>in</u>* 'female soldier' or *Punker<u>in</u>* 'female punk.' Obviously, in languages such as German, Russian, or French, the relation between grammatical gender and lexical gender is anything but arbitrary.

In (grammatically) genderless languages, lexical gender determines the choice of gender-variable pronominal forms, e.g., anaphoric *she* or *he* in English. In the case of gender-neutral nouns, pronominal choice may be determined by the referent's gender, but also by tradition, prescription, or speaker attitude.

Referential Gender

Referential gender relates linguistic expressions to the non-linguistic world and identifies a referent as female, male, or gender-indefinite. For example, a personal noun such as Germ. *Tennisstar* is grammatically masculine, lexically gender-neutral, and may be used to refer to males or females. In (3b), referential gender (female) overrides grammatical gender:

(3) a. *der* *Tennisstar* ... *er*
DET.MASC Tennisstar.MASC PRO.MASC
→ grammatical agreement
b. *der* *Tennisstar* ... *sie*
DET.MASC Tennisstar.MASC PRO.FEM
→ referential agreement

Like *Person* (f) 'person' and *Individuum* (n) 'individual,' the German noun *Star* (m) 'star' belongs to the group of nouns (sometimes called *epicenes*), which are in principle gender-neutral. However, compounds such as *Fußballstar* 'footballstar' and *Pornostar* 'pornstar' are likely to elicit a male or female imagery, respectively. This suggests that the context will affect the noun's connotative semantic specification in various ways, and that many personal nouns have an underlying or covert gender bias.

Social Gender

Personal nouns have social or covert gender if the choice of associated words can neither be explained by grammatical nor by lexical or referential gender. Social/covert gender has to do with stereotypical assumptions about what are appropriate social roles for women and men, including expectations about who will be a typical member of the class of, say, *surgeon* or *schoolteacher*. The term *social*

gender emphasizes the social causes of a noun's gender bias, while *covert gender* refers to its structural invisibility.

An illustration of social gender in English is the fact that many high-status occupational terms such as *surgeon* or *scientist* will frequently be pronominalized by *he* in contexts where referential gender is either not known or irrelevant. By contrast, low-status occupational titles such as *schoolteacher* or *nurse* will often be followed by anaphoric *she* in neutral contexts. In cases of conflict between such practices and actual reference, explicit – and often asymmetrical – gender marking is an optional solution, as in English *woman scientist* or *male nurse*.

Asymmetrical Gender Marking

In principle, and irrespective of whether the language has grammatical gender, lexical or referential gender can be expressed symmetrically in any language, e.g., feminine/female terms can be derived from existing male/masculine terms (4a), and lexical gender nouns can be used in compounding (4b) to create morphologically symmetrical pairs:

(4)			
a.	*Derivation*		
	Masculine/ male	Feminine/ female	
Arabic	*katib*	*katib<u>a</u>*	'secretary'
Norwegian	*forfatter*	*forfatter<u>inne</u>*	'author'
Romanian	*pictor*	*pictori<u>ță</u>*	'painter'
b.	*Compounding*		
	Masculine/ male	Feminine/ female	
English	*congress<u>man</u>*	*congress<u>woman</u>*	
German	*Geschäfts<u>mann</u>*	*Geschäfts<u>frau</u>*	'business man/woman'
Norwegian	*politi<u>mann</u>* police.man	*politik<u>vinne</u>* police.woman	'police officer'

However, female linguistic visibility is often a marked and loaded concept (Baron, 1986), and there is considerable variation concerning the status and productivity of feminine/female word formation processes across languages. Thus, in contrast to German, few derived feminines exist in Welsh (which also has grammatical gender, but no productive feminine/female word formation patterns), and most occupational terms in Welsh are grammatically masculine and have no feminine counterparts (Awbery *et al.*, 2002).

Frequently, the creation of female-specific nouns will produce semantically asymmetrical pairs in which the female represents the lesser category, illustrating what Schulz (1975) has called *semantic derogation*. Notorious examples are English *governor/governess*, *major/majorette*, etc. (Kramarae and Treichler, 1985). Of course, such pairs also occur in languages with grammatical gender:

(5)			
	French	*couturier* (m) 'fashion designer'	*couturière* (f) 'seamstress, female tailor'
	Polish	*sekretarz* (m) '(party) secretary'	*sekretarka* (f) 'secretary (in an office)'
	Swedish	*tjänsteman* (c) service.man 'public servant'	*tjänstekvinna* (c) service.woman 'female servant'

Generally, feminine/female terms are not consistently used; they may be stylistically marked and in many languages carry negative connotations, which makes them unacceptable not only in neutral, but also in female-specific, contexts. Thus, in Russian or Polish, where masculinity is highly valued, feminine/female counterparts of terms denoting prestigious occupations are avoided. By contrast, masculine/male terms are either neutral or carry positive connotations. The implicit ambiguity of masculine/male terms (i.e., their interpretation as either generic or male-specific) explains the fact that combining a gender-neutral noun with a female-specific element is traditional practice, while combination with a male-specific element is the rare exception.

(6)		Gender-neutral term	Gender-specific term
	Icelandic	*skáld* (n) 'poet'	*skáldkona* (f) poet.woman 'female poet' **skáldmaður* (m) poet.man 'male poet'
	Japanese	*kisha* 'reporter'	*joseikisha* woman.reporter 'female reporter'
	Indonesian	*dokter* 'doctor'	*dokter perempuan* doctor woman 'female doctor'
	French	*écrivain* (m) 'writer'	*femme écrivain* (f) 'female writer'

Asymmetrical gender-marking may fulfill various communicative functions: it may emphasize visibility of the 'unexpected' referential gender, define the marked gender as the deviation from the norm, or serve contrastive purposes.

The use of gendered pronouns to refer to inanimate objects may also be discussed in terms of asymmetrical gender-marking, e.g., in English, a boat, motorcycle, airplane, or even a big wave in surfing may be referred to as 'she.' This practice establishes a possessive, i.e., asymmetrical relation between the (stereotypically male) possessor and the 'possessed' object. In the past, hurricanes had female names, were referred to by female pronouns, and associated with stereotypically (negative) female imagery. Today, hurricanes with female names still have female anaphoric pronouns, while hurricanes with male names tend to be followed

by neuter pronouns. This practice reflects on the "larger metaphor in which nature is a woman" (Romaine, 1999: 74). Nature as well as women can be dangerous (or 'uncivilized') and need to be controlled by men. Metaphorical relations have also been established between women and topography.

Again, in English, towns, cities, and countries may be referred to by 'she,' while in a gender language such as German, this relation may be grammaticalized in that the respective nouns belong to the feminine gender class: e.g., *(die) Natur* 'nature', *(die) Wildnis* 'wilderness', *(die) Stadt* 'town' (see also Corbett, 1991: 94). Such practices may be symbolic of the concept of woman as 'the other' which takes an extreme form in discourses of colonialism and war, when physical conquest of a territory may be linked with sexual conquest or rape (Romaine, 1999: 77).

Androcentric 'Generics'

Traditional prescription requires the use of so-called generic masculines (in the case of languages with grammatical gender) or male generics (in the case of grammatically genderless languages) to refer to both men and women. For example, masculine nouns such as Russ. *vrač* (m) 'physician', Fr. *ministre* (m) 'minister', or Arab. *muħami* (m) 'lawyer' may be used to refer to males, groups of people whose gender is unknown or unimportant in the context, or even female referents, illustrating the generic function of masculine nouns.

In languages without grammatical gender, the use of male-biased nouns (*chairman, mankind*) and pronouns (generic *he*) illustrates androcentric practices in cases of gender-indefinite reference. Thus, in English, where gender-variable third person singular pronouns remain of an original grammatical gender system, generic *he* is the prescriptive choice in gender-indefinite contexts such as *an American drinks his coffee black*. While this practice adds to the invisibility of female pronouns, it does not necessarily account for the dramatic imbalance between pronominal references to women and men in texts, where men may be referred to considerably more often than women, e.g., a word count of *he/she* in the Brown corpus of American English yielded a total of 9,543 occurrences of (male-specific) *he* compared with 2,859 of *she* (Romaine, 2001: 161).

Pronominalization is a powerful strategy of communicating gender (Romaine, 2001; Holmes, 2001). Anaphoric gender-variable pronouns may indicate lexical gender, they may function as a means to either specify or abstract from (intended) referential gender, and they may emphasize traditional or reformed practices, as when a speaker makes the choice between a false generic and a gender-inclusive alternative (e.g., Engl. generic *he* vs. singular *they*; Danish *han* 'he' vs. *han/hun* 'he/she', see Gomard and Kunøe, 2003).

In languages that lack even gender-variable pronouns, male generics may be found in the nouns themselves. In Finnish, for example, occupational terms ending in *-mies* 'man' are used to refer to both men and women (e.g., *lakimies* lit. law-man; 'lawyer') and are officially claimed to be gender-neutral.

In languages with grammatical gender, androcentric generics typically occur in coordination, e.g., when a noun phrase conjoins a masculine and a feminine noun, the choice of a related satellite form, e.g., a predicative adjective, may create a conflict between the two competing genders. Examples from Romanian (8a) (Maurice, 2001) and Arabic (8b) (Hachimi, 2001) show that agreement occurs with one conjunct only, namely the masculine:

(8) a. *un* *vizitator* *şi* *o* *turistă*
a visitor.MASC and a tourist.FEM
mult *interesați*
very interested.MASC.PL
'a very interested (male) visitor and a very interested (female) tourist'

b. *Lab* *u* *bnat-u*
father.MASC.SG and daughter.FEM.PL-his
ʕyyan-in.
tired.MASC-PL
'The father and his daughters are tired.'

According to one interpretation the choice of masculine agreement forms in such cases is "evidently of the syntactic type" (Corbett, 1991: 279), claiming that what determines agreement is independent of the meaning of the nouns involved. In an alternative view, the example illustrates the prescriptive practice that if at least one conjunct is headed by a masculine noun, masculine agreement forms are used.

There are occasional exceptions to this prescription. For example, in some gender languages, the neuter gender may be employed to resolve the gender conflict in coordination, as in this example from Icelandic (Grönberg, 2002), where a grammatically neuter form is chosen:

(9) *Óli* *og* *Elsa* *eru* *ung.*
Óli.MASC and Elsa.FEM are young.NEUT.PL
'Óli and Elsa are young.'

Underlying syntactic conventions as in (8) may be a gender hierarchy that defines the masculine as the "most worthy gender" (Baron, 1986: 97). As a result, masculine/male (pro)nouns are highly visible in gender languages and carry considerably more weight and emphasis than feminine/female expressions.

The Psycholinguistic Effects of Androcentric Generics

There is extensive empirical evidence documenting the psycholinguistic effects of androcentric generics; e.g., for English (MacKay and Fulkerson, 1979; Gastil, 1990; Switzer, 1990; Hamilton *et al.,* 1992; Prentice, 1994; Madson and Hessling, 2001) and German (Irmen and Köhncke, 1996; Braun *et al.,* 1998; Rothermund, 1998; Stahlberg and Sczesny, 2001; Rothmund and Scheele, 2004), while there are few experimental studies on other languages, e.g., Braun (2000) on Turkish, and Engelberg (2002) on Finnish.

In experimental studies on English, the focus is necessarily on pronouns (generic *he* and alternatives), while studies on German investigate masculine nouns and alternative formulations. Dependent variables include verbal as well as nonverbal responses: give referent a name, create a story around referent, complete sentences, decide whether an expression can refer to females/males, draw figures, estimate percentage of females in a given group of referents, give judgment on a defendant's criminal offence.

For English, the overwhelming evidence is that generic *he* invokes significantly more male than female imagery, i.e., the concept female is not generally available in the processing of androcentric expressions. The use of generic *he* may in fact have dramatic practical consequences: Hamilton *et al.* (1992) found that the use of generic *he* in instructions to a jury led jury members to interpret a defendant's criminal offense significantly more often as manslaughter or murder, while the same text using gender-inclusive wording resulted in a higher percentage of interpretation as self-defense.

The German studies tested generic masculine nouns as compared to reformed alternatives, esp. nominal splitting (e.g., *Bürger und Bürgerinnen*; *Bürger/innen* 'citizens'), neutral expressions (e.g., *die wissenschaftlich Tätigen* 'scientists), and the so-called *internal I* (as in *BürgerInnen* 'citizens,' an abbreviated form of *Bürger und Bürgerinnen*). The use of masculine generics was found to produce overwhelmingly more male-specific imagery. By contrast, long splitting appears to achieve a roughly symmetrical mental representation of female and male referents. Interestingly, the variant 'internal I' tended to evoke an overly female mental imagery. It seems that this variant has the effect of a politically correct symbol signaling a pro-feminist attitude (Stahlberg and Sczesny, 2001: 138). Finally, the practice of adding a footnote to a text explaining that the masculine generics used in the text are intended to include women turned out to be totally unsuitable as a reform measure. Informants rather felt relieved of the burden to speculate about potential female participation in a text (Rothmund and Scheele, 2004: 8). In languages with grammatical gender, the only way of significantly increasing the availability of the concept female in a text seems to be the use of multiple female-specific expressions.

Language Politics: Guidelines for Non-sexist Language

From the 1970s, feminist linguistic activists in the United States and Western Europe began to document sexist language practices and develop proposals for non-sexist alternatives (Frank and Treichler, 1989; Pauwels, 2003). Often, such recommendations took the form of guidelines that were adopted by publishing houses, professional organizations, academic institutions, the print media, etc. (for English see: NCTE, 1985; UNESCO, 1989; APA, 1994; APhilA, 2003; for German: Hellinger and Bierbach, 1993; Kargl *et al.,* 1997; Häberlin *et al.,* 1998). Frequently, explicit reference was made to the respective national legislation on Sex Discrimination, Equal Opportunity, and Human Rights Acts, maintaining that the equal treatment of women and men must also be realized on the level of communication.

Reform measures in international organizations tend to be moderate. While in 1989 UNESCO produced the *Guidelines on non-sexist language* (UNESCO, 1989), in 1994, the UNESCO Executive Board once again discussed the question of the elimination of sexist language from all UNESCO Basic Texts (which must all be produced in UNESCO's six working languages, i.e., English, French, Spanish, Russian, Arabic, and Chinese). The General Conference adopted a resolution stating its conviction that gender-neutral wording "may alter attitudes and expectations that now constitute a barrier to achieving equality of opportunity for women and men" (UNESCO, 1994: 1). However, the practical consequences of the reform measures were minimal, because non-discriminatory replacements for male/masculine generics in UNESCO's six working languages were largely modeled on English. Thus, only a small number of androcentric personal nouns were replaced by gender-inclusive alternatives, e.g., Engl. *(chair)man, mankind* → *(chair)person, humanity*; Fr. *homme* → *la personne humaine, l'individu*; Span. *hombres* → *los seres humanos, las personas*. Neutralization is the favored reform strategy, in spite of the fundamental structural differences between UNESCO languages concerning grammatical gender, the productivity of feminine/female word formation processes, and the number of gender-variable pronouns. It is claimed that the continued linguistic invisibility of women is no problem in the

languages with grammatical gender (French, Spanish, Russian, and Arabic) because "the generic use of the masculine form for post titles for both sexes is considered acceptable" (UNESCO, 1994: 4). In fact, a decision was made to the effect that all UNESCO documents must simply carry a footnote explaining that any person-denoting term is to be interpreted as referring equally to women and men. This ignores the empirical evidence that has proved the generic potential of personal masculines to be a myth.

In Europe, in 1990, the Committee of Ministers of the Council of Europe adopted the UNESCO recommendations on the use of non-sexist language, and in 2003, the European Parliament recalled that "the sexism reflected in language is an obstacle to equality between men and women" (EU, 2003: 8). The use of non-discriminatory language in all EU documents was mandatory, "since equality is one of the democratic values of the European Union" (EU, 2003: 30). So far, this rhetoric has had minimal practical consequences.

As an instrument of language planning, guidelines for non-sexist usage symbolize the dissonance between traditional prescription and reformed usage. Gender-inclusive formulations question the *status quo* which supports the use of masculine/male generics to refer to both sexes. Public responses frequently reveal openly hostile reactions maintaining that reformed usage violates grammar, is cumbersome and unaesthetic, and interferes with freedom of speech (Cameron, 1995: 132; Blaubergs, 1980; Hellinger, 2000). By contrast, proponents of reformed usage adhere to various degrees of linguistic relativity, suggesting that a change in behavior, i.e., using more instances of non-sexist language, will enlarge the mental space of female imagery and weaken the male-as-norm ideology, thus contributing to social change. The ongoing debate on (non)sexist language must be interpreted as part of the ongoing political discourse over the equal participation of women in all public domains.

The choice of non-sexist alternatives presents relatively minor problems in languages such as English, Turkish, Finnish, Chinese, or Japanese, which possess few gender-variable forms, and will therefore tend toward neutralization, while more female visibility is expected in gender languages such as French or Russian. However, the structural properties of a language are no sufficient basis for making the choice between feminization, neutralization, or a mixed strategy. Perhaps of equal importance in feminist language planning will be non-linguistic parameters pertaining to the specific historical, sociocultural, and ideological context of the language. Issues such as the following must be addressed:

- Does the country have a tradition of language planning? For example, in Greece, language planners are preoccupied with the implementation of the new, no longer diglossic situation and the standardization of the demotic variety of Greek, rather than with the unequal linguistic treatment of women and men (Pavlidou, 2003: 189).
- Does the country have influential key agents (individuals and organizations) who are accepted as innovators or supporters of change?
- Is there a tradition of purist attitudes which would encourage rejection of any change?
- Does the country have a major feminist movement, and if so, has the feminist critique of language been recognized as an arena of political discourse?

Another factor that may have an impact on feminist language planning is the dominance of English. Recommendations to avoid female visibility in Italian have been linked to an adoption of Anglo-American models (Marcato and Thüne, 2002: 210). Female visibility is also rejected for Welsh, where the creation of new personal feminines has been interpreted by the Welsh minority as linguistic imperialism from the dominant English language (Awbery *et al.,* 2002: 328). Similarly, it is not unlikely that the impact of German in Eastern Europe will be an issue in the emerging feminist critique of language in the Czech Republic, Poland, and Russia (Koniuszaniec and Błaszkowska, 2003: 279).

Changes in language practices do not necessarily reflect the intentions of feminist activists or official guidelines. In German, the disappearance of *Fräulein* 'Miss' as a term of address for female adults has in fact created a symmetrical pair of address terms (*Herr/Frau*), but in English, the creation of *Ms* as a title that would transport no information on the referent's marital status, has not replaced *Miss*. And although a significant increase in the usage of *Ms* among Australian women has been reported between 1987 and 1996, users do not necessarily share the term's understanding. In addition to the promoted meaning, *Ms* transports a number of unintended meanings, from 'separated/divorced,' 'living in a *de facto* relationship,' to 'feminist,' or 'lesbian' (Pauwels, 2001: 142).

Generally, however, at least for English and a few Western languages, a decrease of male/masculine generics in favor of non-sexist alternatives can be observed (Cooper, 1984; Ehrlich and King, 1994; Pauwels, 1998). A study on public discourse among American economics leaders found a sharp decline in sexist usage since the 1970s (Rubin *et al.,* 1994). Also, many young people produce more gender-neutral or inclusive language, but this may not

necessarily be connected with a pro-feminist attitude. However, non-sexist language reform will only be successful if changed practices are a reflection of the user's awareness of the discriminatory nature of traditional prescription, and of a personal commitment to change (Pauwels, 2003). Linguistic choices remain symbolic of different beliefs and ideological positions.

Sextus Empiricus (fl. 200 A.D.)

P Swiggers and A Wouters, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Given the scarcity of (direct and indirect) sources on Sextus Empiricus's life and work, it is possible only to situate him roughly in the second half of the second and the first quarter of the third century A.D. Sextus may have been of North African origin; he seems to have known well Athens, Cos, and also Rome, where he taught for some time.

A physician and adherent of the Greek empirical school, Sextus Empiricus is especially known for his philosophical work (transmitted in manuscripts of the Middle Ages). A follower of Pyrrho (360–270 B.C.), Sextus became one of the most eloquent and radical defenders of philosophical scepticism. His views are expounded in three books entitled 'Outlines of Pyrrhonism' (*Purrhoneiai hypotuposeis*), which constitute an introduction to scepticism and offer a critical analysis of the foundations of logic, ethics, and natural philosophy, and in his 'Against the Professors' (*Pros mathematikous*), a collection of 11 treatises (not written in the order as they were definitively organized by Sextus: VII-XI were written before I-VI), in which he raises doubts about the principles, the specific place and importance, the usefulness, and the teaching (and teachers), of the following disciplines: grammar, rhetoric, logic, physics, ethics, geometry, arithmetic, astronomy, and music.

The highly entertaining first treatise against the grammarians (*Pros grammatikous*), while recognizing the important (social and cognitive) role of language, is a vehement attack on Stoic philosophy of language (which is also critically dealt with in the treatise against the logicians) and on Alexandrian grammar. Sextus adopts a common-sense and anti-mentalist view of language, a pragmatic view of linguistic correctness (successful communication being the yardstick of correctness), and an anomalist (antianalogist) view of the nature of language (use and description of language should follow natural acquisition and custom, and not an *a priori* conception of language regularity); Sextus excels in ridiculing the grammarians' theoretical pretensions and blaming them for their ignorance about words used in poetry and their meanings. Pyrrhonian scepticism is combined here with elements of Epicurean philosophy (stressing the primacy of naturalness). Sextus Empiricus's criticism of 'technical' grammaticography follows the structure of the ancient grammatical manuals (*technai*

The Republic of Seychelles comprises about 100 islands off the East African coast in the Indian Ocean. Originally settled by French settlers and slaves, the islands were under British rule from 1794 until independence in 1976. French and English are the colonial languages of the islands, and are widely used, but the main language is Seychellois Creole (Seselwa Creole French), which is spoken by more than 95% of the population. While Seychellois Creole had little prestige under colonial rule, it became the first official language (with English second and French third official language) after independence, and has increasingly been developed through standardization and the development of an orthography and teaching materials. Seychellois Creole is used in primary education as a medium of instruction. All three official languages are found in the media and all are official languages of parliament.

Sgall Petr (b. 1926)

S Archaimbault, University of Paris, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Petr Sgall, born in 1926 in Cheske Budejovice (Southern Bohemia), graduated from Charles University in Prague with a degree in General and Indo–European Linguistics. Appointed Teaching Assistant in 1958, he began studies toward a Ph.D. in mathematical linguistics, which he obtained in 1966. From then on, he devoted himself to the development of formal and computational linguistics, in relation to the development of automated translation. At the end of the 1950s, he set up a team at Charles University, located first at the Faculty of Literature, then at the Faculty of Mathematics and Physics. In 1967, he was appointed Research Director in Theoretical Linguistics and Natural Languages Automated Treatment within the Faculty of Mathematics and Physics. In 1990, he became Professor of General Linguistics within the Faculty of Literature and Human Sciences. Petr Sgall has also been Director of the Laboratory of Algebra Linguistics from 1968 on, and, since 1990, Director of the Institute of Theoretical and Automated Linguistics.

Petr Sgall became famous as a theoretical linguist, specializing in natural languages automated treatment, from the viewpoint of linguistics as well as that of logic or mathematics. His work covers the fields of morphology, but also syntax and the relations

between semantics and pragmatics. His ultimate achievement is his definition and development of the 'Generative Functional Description' (GFD), strongly anchored within the Prague tradition, of which Petr Sgall is a specialist and a prominent contemporary representative. However, his research interests are much wider, since they encompass language typology, sociolinguistics, and, above all, Bohemistics, with a special interest in common contemporary Czech.

From 1961 on, when the first automated translation experiment was carried out in Prague, Petr Sgall worked on the definition of the consistent theoretical framework of GFD, seeking contiguities with research projects in that field all over the world (developments of the Chomskyan model, unification formalisms, LFG, meaning-text model, etc.).

The GFD contributed to linguistic knowledge

1. by describing the verb as the sentence nucleus, and also describing its relation to agents and adverbials, and then to its internal and external participants, whether they can combine freely with any verb or obey constraints relating to the verbal frame of certain lexical units;
2. by the research on the present division, which is treated in many articles. The conclusions are that word order is not free whatsoever, even in Slavonic languages, and that the definition of the separation topic, or focus, in relation to the scope of negation, helps rule out the homonymic ambiguity on the surface level;
3. by finally establishing stable criteria for sentence synonymy.

In the field of applications, the work of the team coordinated by Petr Sgall focused on the systems of automated information search, in free texts (MOZAIKA) or in textual databases (ASIMUT), also on the automated understanding of texts (TIBAQ: Text and Inference-Based Answering of Questions), and, of course, on automated translation, with the APA system of English/Czech translation and the Czech-to-Russian RUSLAN system. The team also took part in the MATRACE project, started by IBM.

Although he officially retired on October 1, 1992, Petr Sgall, as Emeritus Professor, is still very active within the Theoretical and Mathematical Institute and the Institute of Formal and Applied Linguistics, now run by Eva Hajiová with whom he co-edits the series *Studies in Functional and Structural Linguistics* published by John Benjamins in Amsterdam.

Shared Knowledge

A Capone, Barcellona, Italy

© 2006 Elsevier Ltd. All rights reserved.

What is it to know a proposition? A person A knows that proposition p if and only if (iff):

A believes that p;
A is justified in believing that p;
p is true.

So there are three clauses that must be satisfied for a state of knowledge to be correctly ascribed to A. To explicate each of the three clauses would be a Herculean task, for the first clause would require a theory of propositional attitudes, the second clause would require a theory on what counts as appropriate justification for a belief, and the third clause requires a theory of truth. We accept, without making a real effort to justify it, the idea that for A to believe a proposition p is to be in a mental state that is likely to influence A's conduct; we also accept that a person has appropriate justification for a belief if he or she has canonical evidence guiding him or her toward ascertaining the truth; we accept that a proposition

between semantics and pragmatics. His ultimate achievement is his definition and development of the 'Generative Functional Description' (GFD), strongly anchored within the Prague tradition, of which Petr Sgall is a specialist and a prominent contemporary representative. However, his research interests are much wider, since they encompass language typology, sociolinguistics, and, above all, Bohemistics, with a special interest in common contemporary Czech.

From 1961 on, when the first automated translation experiment was carried out in Prague, Petr Sgall worked on the definition of the consistent theoretical framework of GFD, seeking contiguities with research projects in that field all over the world (developments of the Chomskyan model, unification formalisms, LFG, meaning-text model, etc.).

The GFD contributed to linguistic knowledge

1. by describing the verb as the sentence nucleus, and also describing its relation to agents and adverbials, and then to its internal and external participants, whether they can combine freely with any verb or obey constraints relating to the verbal frame of certain lexical units;
2. by the research on the present division, which is treated in many articles. The conclusions are that word order is not free whatsoever, even in Slavonic languages, and that the definition of the separation topic, or focus, in relation to the scope of negation, helps rule out the homonymic ambiguity on the surface level;
3. by finally establishing stable criteria for sentence synonymy.

To explicate each of the three clauses would be a Herculean task, for the first clause would require a theory of propositional attitudes, the second clause would require a theory on what counts as appropriate justification for a belief, and the third clause requires a theory of truth. We accept, without making a real effort to justify it, the idea that for A to believe a proposition p is to be in a mental state that is likely to influence A's conduct; we also accept that a person has appropriate justification for a belief if he or she has canonical evidence guiding him or her toward ascertaining the truth; we accept that a proposition

p is true if the world conforms to some mental state p or some fact p or if p is a proposition accepted by convention or stipulation within a certain society.

Having defined knowledge in this way, we are able to refute the skeptics and in particular to counter the skeptics' attacks on shared knowledge. From the fact that knowledge can be revised, we should not deduce that there is no knowledge or no shared knowledge.

What is shared knowledge? An intuitive definition could be one like the following: two persons, A and B, share knowledge of a proposition p iff they both know that p and if they both know that the other knows that p and that B knows that A knows that B knows that p and A knows that B knows that A knows that p. In other words, shared knowledge is not just knowledge on A's part that the other person, B, knows a proposition p that A also knows, but also knowledge that the other person knows that A knows that p. The definition does not necessarily generate infinite recursion; a regress of the second or third order may suffice for the purpose of practical understanding. In any case, even infinite recursion can be finitely represented, albeit not at the conscious level (a simple mathematical example is the case of recursion in 3.3 periodical).

How can shared knowledge be obtained? Shared knowledge can be constructed through shared perceptual stimuli or through publicly vocalized utterances. Suppose you and I stand in front of the Statue of Liberty in New York City: both of us see the imposing statue, and there is little doubt that it does not escape our attention; we are confronted with something that we cannot but see. Shared knowledge can also be constructed linguistically, by referring to an authority, or in general, to human linguistic productions.

Of course, shared knowledge is a testable assumption; one assumes it to be present unless there are overwhelming reasons for doubting that things are as they are assumed to be. It is possible, albeit unlikely, that you are momentarily blinded, that I do not realize that fact, and that I erroneously assume that you know that the Statue of Liberty is there in front of you; however, this assumption can easily be tested by analyzing your reply (or absence of reply) to my casual remark, as when I say "That statue is impressive"; in the absence of an appropriate reply, I realize that the presumption of shared knowledge was not justified. But this is not the way we standardly proceed. We just assume that salient visual (and other) stimuli are part of our shared knowledge, and we do not put this assumption to the test.

Shaw, George Bernard (1856–1950)

M Net, Bucharest, Romania

© 2006 Elsevier Ltd. All rights reserved.

George Bernard Shaw is chiefly known as a world-famous playwright who won the Nobel prize for literature in 1925. He was also a critic of music, art, and drama, as well as a defender of Fabian socialism. His plays, articles, prefaces, and public pronouncements programmatically challenge the accepted ideas of what he used to call "middle class respectability" (*Pygmalion*, Act I).

Shaw is included in the present encyclopedia owing to his interest in language use in various contexts, social strata, and milieus, and especially for his concern with elocution, phonetics, and spelling. Shaw

Shaw, George Bernard (1856–1950)

M Net, Bucharest, Romania

© 2006 Elsevier Ltd. All rights reserved.

George Bernard Shaw is chiefly known as a world-famous playwright who won the Nobel prize for literature in 1925. He was also a critic of music, art, and drama, as well as a defender of Fabian socialism. His plays, articles, prefaces, and public pronouncements programmatically challenge the accepted ideas of what he used to call "middle class respectability" (*Pygmalion*, Act I).

Shaw is included in the present encyclopedia owing to his interest in language use in various contexts, social strata, and milieus, and especially for his concern with elocution, phonetics, and spelling. Shaw

even made explicit provisions in his will for funding the development of a new, phonetically based English alphabet.

Shaw was born in Dublin on July 26, 1856, into a family of Irish Protestants. After graduating from a business college, he worked for a brief span in his native city. In 1876, he settled in London. By the end of his life, Shaw lived mostly at Ayot, St Lawrence, Hertfortshire.

During his first nine years in London, Shaw earned no money. While attending some lectures at University College, London, he met F. J. Farnivall from the New Shakespeare and Philological Societies, who commissioned him to write the index and glossary of the Hunterian Club edition of Thomas Lodge's works.

At the beginning of his literary career, Shaw wrote five novels but did not manage to sell any. His first play, *Widowers' House* (performed in 1892) passed almost unnoticed. Nevertheless, during his lifetime, Shaw wrote more than 50 other plays, most of them successful. He got into the habit of publishing them preceded by his own prefaces.

Shaw's interest in phonetics was first aroused by a nephew of Alexander Melville Bell, the inventor of 'visible speech.' In 1979, Shaw also got to know Henry Sweet, with whom he corresponded on topics related to phonetics. Shaw was to be inspired by both Sweet and Daniel Jones when he created the famous character of Henry Higgins.

In his *Three Plays for Puritans* (1901), Shaw made a few innovating (therefore rather shocking) remarks on the Cockney dialect. Then Shaw also launched a newspaper campaign for what he considered a more rational orthography.

Similarly, in Act II of *Major Barbara* (1901), he introduced a passage of dialect transliterated in the international phonetic alphabet; then he translated it back into standard English (for the use of the uninitiated readers) and eventually resumed his habit of giving a phonetic approximation of the characters' pronunciation by using the symbols of the conventional alphabet. This kind of respelling has been always challenging (to say the least) to both actors and readers.

Pygmalion (Shaw's best-known play) was characterized by the author himself as "a play about phonetics" (*apud* Ducat, 1859: 59). It was first published in German in 1913. Later in that same year, its original version is generally considered one of the greatest hits yet registered on the English stage (though nowadays it is better known to audiences all over the world via F. Löwe's musical *My Fair Lady* and via the even more renowned musical film of the same title, featuring Audrey Hepburn and Rex Harrison). Shaw's play raises interesting questions concerning the complex relationship between the use of language, on the one hand, and education, manners, fashion, social strata, and cultural values, on the other hand. The relation between gender and language (quite fashionable at the time) is also considered.

Pygmalion is also connected to one of Shaw's best-known dictums on speech. In 1942, he added the following sentence to his preface to this play: "it is impossible for an Englishman to open his mouth without making some other Englishman despise him." Presumably, this bitter pronouncement originated from the eight years Shaw spent as chairman of the Advisory Committee on Spoken English to the British Broadcasting Company. The acknowledged aim of the Committee was to advise announcers on the pronunciation required by the BBC; nevertheless, it contributed a great deal to establishing a standard 'BBC English' (received pronunciation), which became the accepted norm with most speakers of English.

It had been Shaw's lifetime desire to establish a new English alphabet. In 1944, he advertised his wish to set up a trust that would empower the executors of his will "to finance any promising scheme for providing a new phonetic alphabet capable of expressing the fourty-two sounds listed by the late Henry Sweet" (*apud* Pearson, 1981: 434). In case the project failed, the money was meant to be spent on other enterprises of public interest. Shaw's campaign was unsuccessful, and the Simplified Spelling Society (the only authority entitled to put it into practice) openly opposed the project.

After Shaw's death, two of his official legatees (the Royal Academy of Dramatic Art and the British Museum) contested the will by which Shaw had left most of his huge fortune for research on this new alphabet. Due to lack of funds, the only concrete result of Shaw's project concerning the simplification of English spelling is an edition of his play *Androcles and the Lion* transliterated in a hybrid alphabet based on Kingsley Read's system of 48 graphemes.

Shaw's ideas about pronunciation and spelling seem to have no future.

Shcherba, Lev Vladimirovich (1880–1944)

S A Romashko, Russian Academy of Sciences, Moscow State University, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

Graduating in 1903 from St Petersburg University, Lev Vladimirovich Shcherba was a pupil of J. Baudouin de Courtenay. He spent 1906–1909 in western Europe, in Germany, France, and Italy. In Leipzig, he attended the lectures of E. Sievers; and in Paris, he worked in the phonetic laboratory of J. P. Rousselot. He studied Italian dialects in Northern Italy, and Sorbian, the language of a Slavic minority, in Germany. In 1909, he resumed his activity at St Petersburg University, where he was appointed the head of the laboratory of instrumental phonetics, which for a long time was the main center of phonetic studies in Russia. He published his first substantial work in phonetics, considering Russian vowels (Shcherba, 1912), and a description of the Sorbian subdialect that he studied in Germany (Shcherba, 1915). In 1916, he became a professor at St Petersburg/Petrograd (later Leningrad) University and remained in this position till 1941. In 1923, he was elected a corresponding member of the Academy of Sciences, and he became a full member of the Academy in 1943. In 1941, after Leningrad was besieged during World War II, he was transferred to Moscow, where he spent his last years.

Developing the ideas of J. Baudouin de Courtenay on 'psychophonetics,' Shcherba took a substantial step in phonology, pointing to the distinctive function as a main function of the phoneme. However, phoneme was for him not an abstract construct, but an acoustic reality. His phonological theory was in synch touch with his phonetic work (he had written, beside his publications on Russian phonetics, a fundamental work on French phonetics, cf. Shcherba, 1937). Shcherba's ideas made an impact on other Russian scholars, including R. Jakobson and N. S. Trubetzkoy, who continued their activity after emigrating from Russia. He founded the Leningrad/Petersburg phonological school, being till now (parallel to the Moscow version of phonology), one of two main Russian phonological schools.

In the field of general linguistics, Shcherba reviewd Saussure's distinction between *langage*, *langue*, and *parole*, proposing his own triple division of the object of linguistics: linguistic activity, linguistic system, and linguistic material. The investigation of a living language should be, according to Shcherba, a sort of experimental research. He combined theoretical work with practical tasks; he was a practical lexicographer (cf. his Russian–French dictionary: Shcherba and Matusevich, 1936) and at the same time wrote *A tentative general theory of lexicography* (1940); he also wrote on his applied work on orthography, transcription, etc., with *Theory of Russian writing system* (posthumous, cf. Shcherba, 1957: 144–179).

Sheridan, Thomas (1719–1788)

L C Mugglestone, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Thomas Sheridan (1719–1788), actor, stage manager, and elocutionist, was a prominent writer on education and elocution in the second half of the 18th century. Born in Capel Street, Dublin, he was the third son of the eminent schoolmaster Thomas Sheridan (1687–1738) and the godson of Jonathan Swift. Swift's strictures on the importance of the spoken language strongly influenced the young Sheridan's choice of career; an exchange between the two while Sheridan was studying at Trinity College, Dublin, revealed Swift's belief that education was 'nothing' unless it also included instruction in how to speak. This conversation "particularly sunk deep into my Mind," Sheridan noted in his *Life of the Rev. Dr. Jonathan Swift* (1784). While he was also a successful actor and theater manager, both in Dublin and in London (see Sheldon, 1967), much of Sheridan's later work involved the attempt to integrate elocution and education, beginning with his *British education: or, the source of the disorders of Great Britain* (1756), and continuing in a range of subsequent publications including his *Lectures on the art of reading* (1761), his *Course of lectures on elocution* (1762), and his *Elements of English* (1786), a work in which he attempted to translate his educational theories into a format that could be applied in the very first stages of instruction. Language was, Sheridan stressed, "my chief object in life, and the centre to which all my views tended"; his chosen role was as a reformer of both language and language attitudes. To this end, he gave numerous well-attended lecture tours throughout the nation, as well as being a sought-after private tutor in the arts of elocution. James Boswell was taught by him in his own attempt to shed his Scottish accent, as was Lord Alexander Wedderburn and Lord Loughborough (later the Lord Chancellor). Sheridan was given honorary degrees by both Cambridge and Oxford, as well as the freedom of the city of Edinburgh. As the title page of Sheridan's *General dictionary of the English language* (1780) indicates, the attempt to fix pronunciation was one of his major aims—the dictionary was, he stated, intended "to establish a Plain and Permanent Standard of Pronunciation." Like a number of other writers in the late 18th century, Sheridan was perplexed by the geographical and social variabilities of English pronunciation and desired instead to secure a uniformity of speech throughout the nation. While Samuel Johnson derided his attempt to integrate the teaching of a standard of pronunciation in the dictionary (his own *Dictionary* of 1755 had merely marked the main position of stress), Sheridan's influence was significant and can be detected in many of the educational writings and textbooks produced over the 19th century.

Sheridan, Thomas (1719–1788)

L C Mugglestone, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Thomas Sheridan (1719–1788), actor, stage manager, and elocutionist, was a prominent writer on education and elocution in the second half of the 18th century. Born in Capel Street, Dublin, he was the third son of the eminent schoolmaster Thomas Sheridan (1687–1738) and the godson of Jonathan Swift. Swift's strictures on the importance of the spoken language strongly influenced the young Sheridan's choice of career; an exchange between the two while Sheridan was studying at Trinity College, Dublin, revealed Swift's belief that education was 'nothing' unless it also included instruction in how to speak. This conversation "particularly sunk deep into my Mind," Sheridan noted in his *Life of the Rev. Dr. Jonathan Swift* (1784). While he was also a successful actor and theater manager, both in Dublin and in London (see Sheldon, 1967), much of Sheridan's later work involved the attempt to integrate elocution and education, beginning with his *British education: or, the source of the disorders of Great Britain* (1756), and continuing in a range of subsequent publications including his *Lectures on the art of reading* (1761), his *Course of lectures on elocution* (1762), and his *Elements of English* (1786), a work in which he attempted to translate his educational theories into a format that could be applied in the very first stages of instruction. Language was, Sheridan stressed, "my chief object in life, and the centre to which all my views tended"; his chosen role was as a reformer of both language and language attitudes. To this end, he gave numerous well-attended lecture tours throughout the nation, as well as being a sought-after private tutor in the arts of elocution. James Boswell was taught by him in his own attempt to shed his Scottish accent, as was Lord Alexander Wedderburn and Lord Loughborough (later the Lord Chancellor). Sheridan was given honorary degrees by both Cambridge and Oxford, as well as the freedom of the city of Edinburgh. As the title page of Sheridan's *General dictionary of the English language* (1780) indicates, the attempt to fix pronunciation was one of his major aims—the dictionary was, he stated, intended "to establish a Plain and Permanent Standard of Pronunciation." Like a number of other writers in the late 18th century, Sheridan was perplexed by the geographical and social variabilities of English pronunciation and desired instead to secure a uniformity of speech throughout the nation. While Samuel Johnson derided his attempt to integrate the teaching of a standard of pronunciation in the dictionary (his own *Dictionary* of 1755 had merely marked the main position of stress), Sheridan's influence was significant and can be detected in many of the educational writings and textbooks produced over the 19th century.

Shinmura, Izuru (1876–1967)

F Katada, Waseda University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Izuru Shinmura, the most senior founder of the Linguistic Society of Japan and the earliest and most prominent lexicographer of Japanese, was born on October 4, 1876, in Yamaguchi, Japan. At the age of 8 he began to study Sinology which had a lasting influence on his entire scholarly life. He studied linguistics at the Department of Philology of the Imperial University of Tokyo (1896–1899) under Kazutoshi Ueda. In 1907, as a Japanese government grantee, he was sent to Europe for two years to study linguistics; he returned to the Imperial University of Kyoto as Professor of Linguistics (1909–1936) and Professor Emeritus thereafter. He was awarded a Doctor of Literature by recommendation in 1910, a year before he became director of the University Library (1911). He was the first president of several academic societies, most notably the Linguistic Society of Japan (founded 1938), the Dialect Society of Japan (founded 1941), and the East Asian Academic Society (founded 1942). Among the numerous honors conferred upon him are Member of the Imperial Academy (1928), First Order of the Sacred Treasure (1936), Cultural Medal (1956), commendation of distinguished Culture Service (1956), and Honorary Citizen of Kyoto (1956). Shinmura died in 1967 at the age of 91.

Shinmura recalled November 10, 1894 as a decisive day in his professional life. He was inspired by the lecture given that day by Kazutoshi Ueda entitled 'Hakuseki Arai as a linguist.' Arai (1657–1725) was a Confucian scholar, a politician, and, most importantly, the author of *Toga* (1719), the pioneering masterpiece of an etymological dictionary of Japanese. This lecture, given from the Western linguistic point of view, led Shinmura to historical linguistics and to study French, Greek, Latin, and languages of Asia, including those of India and China and Ainu.

Throughout his work, which resulted in a series of dictionaries of Japanese, Shinmura's abiding interest and method were descriptive rather than prescriptive, and historical, comparative, and etymological; he laid the foundation for Japanese linguistics, adopting the German linguistic methodology of the time. *Kojien* ('A wide garden of words') is his monumental masterpiece, a widely sold encyclopedic dictionary of the Japanese language, which has evolved, since its first edition (1955), into the 5th edition (1998); this latest edition is about 3000 pages, containing approximately 230 000 lemmata and 2800 figures and illustrations. Shinmura's other research includes works on the history of Christian culture in Japan, the history of Eastern languages, and the etymology of East Asian languages and has also resulted in a number of masterpieces. His scholarship contributed significantly to the development of Japanese linguistics and cultural life.

The Shinmura Izuru Memorial Foundation was founded in Kyoto in 1981. The Shinmura Izuru Prize has been awarded annually since 1982 to outstanding research achievements on the Japanese language.

Shintō

I Reader

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 7, pp. 3875–3876, © 1994, Elsevier Ltd.

Shintō, the indigenous religion of Japan centered on the relationship between the Japanese people and the native deities, *kami*, is closely associated, both at national and local community levels, with issues of Japanese identity and with social and cultural belonging. With no fixed doctrines, its focus is primarily expressed in ritual actions that are concerned with the celebration and promulgation of life, and with issues of spiritual purity and ritual performances that uphold and maintain the relationship between the human world and the world of the *kami*. Although its influence on the Japanese language has never been as pronounced as that of the imported religion Buddhism (see *Buddhism, Japanese*), it has nonetheless played a role in the development of philological studies in Japan as well as producing important texts and specialist vocabulary.

Shintō: Meaning and Derivation

The word '*Shintō*' itself comes from two Sino–Japanese ideograms in their *on* (Japanese approximations of the original Chinese) readings. The first, *shin* (Chinese *shen*), also has the Japanese reading *kami*, the word used to refer to Shintō deities or powers, and the second *tō* (Chinese *tao* or *dao*), whose *kun* or Japanese reading is *michi*, means 'way' or 'path.' Together they signify the *kami no michi*, or *Shintō*, the 'way of the *kami*,' a word developed to identify the rather amorphous and undifferentiated native Japanese religious tradition centered on its native *kami* from the new religious entities and traditions, notably Buddhism, that were introduced to Japan from the Asian mainland from the sixth century AD onwards. Shintō as a named and identifiable entity thus evolved as a result of this cultural interaction with the outside. Although thereby identified as separate from the continental traditions and as specific to the Japanese experience, Shintō has generally existed in tandem with Buddhism in a mutually interpenetrating process. This interpenetration has not, however, prevented each from retaining its separate identity and form, including specialized linguistic forms.

Textual Traditions, Forms of Prayer, and Linguistic Specialities

The introduction of Buddhism and the Chinese writing system provided the means by which a Shintō textual tradition and prayer forms specific to Shintō could be established and recorded. Because the myths and legends associated with Shintō were written at the instigation of the Imperial Court, they tended to legitimate the rule of the Imperial household as well as posit a special relationship of descent between the Japanese and their *kami*. The major text, the *Kojiki* or 'Record of Ancient Affairs,' and the *Nihon Shoki* or *Nihongi* ('Chronicles of Japan'), were written in the early eighth century in a Classical Japanese style strongly influenced by Chinese (indeed the *Nihongi* also contains sections from Chinese and Korean classical works) and describe the creation of Japan by the *kami*, the prominence of Amamterasu the Sun Goddess, and the descent of the Imperial lineage from her.

The adopted writing system provided the vehicle through which to record the *norito*, the sacred incantations and prayers used in Shintō rituals. According to the *Kojiki*, the first *norito* date from the mythical period of Japanese history described in the *Kojiki*, although in reality the earliest recorded extant examples only date to the early tenth century. *Norito* developed their own specialized style and linguistic structure, making use of the textual form of ideograms but adopting it into a style specific to Shintō ritual and terminology. In particular they used Chinese ideograms not simply in terms of meaning but also as phonetic devices: various grammatical nuances, such as verb endings and particles were denoted by ideograms inserted in the text in reduced size, to indicate that they were to be read for their sound rather than meaning. While the use of ideograms indicates the extent to which the indigenous religion was dependent on the linguistic forms provided by the adopted writing system to express itself, the specialized structure of *norito* equally reflects a dynamic within Shintō to create its own linguistic forms that could continue to differentiate it from Buddhism.

Shintō has also developed its own ritual vocabulary that serves to distinguish it both from Buddhism and from everyday affairs. Much of this revolves around taboos, either of words associated with death (a taboo subject in Shintō) or of words associated with Buddhism. In ritual terms, also, specialized Shintō terms are used for everyday words so as to

differentiate them from ordinary life and transpose them to the purified realms of the *kami*. Many foodstuffs, for example, which are important offerings in Shintō rites, have Shintō as well as ordinary names: rice wine, for example, is normally known as *sake* but in Shintō contexts is called *miki*.

Linguistic Studies and the Purity of Language

Its close associations with Japanese identity have often placed Shintō in the forefront of moves to assert the indigenous culture over and against any external influences. Shintō itself was largely an amorphous tradition until attempts were made by various scholars and nationalists from the eighteenth century onwards to codify it as part of a wider design to distinguish Japanese from Chinese and continental influences in Japanese culture, and to attempt to assert the superiority of the former over the latter. Prominent in this was Motoori Norinaga (1730–1801) whose studies of early Japanese texts and pre-Buddhist Japanese as part of his endeavors to assert the culturally unique content of Shintō were – despite their chauvinistic themes – a major starting point for modern philological understandings of the Japanese language.

In the following centuries until 1945, Shintō was a focal rallying point for successive governments in their attempts to assert the purity of Japanese cultural identity over and against the outside world, and this led to further codifications of Shintō and the formation of state Shintō (*kokka Shintō*). While the attempts made by the government, especially in the 1930s and 1940s, to 'purify' Japanese by excising foreign loanwords have no direct and overt connection to Shintō in religious terms, the close association between the Shintō of that period and the state, and Shintō's association with and legitimation of concepts of Japanese national identity, did mean that Shintō had some influence in this issue.

Since 1945 and the legal separation of religion and state, Shintō has reverted more clearly to its basic connections with local communities and with rites, festivals, and celebrations. Nonetheless, its continuing and underlying associations with issues of purity and identity mean that its potential as a rallying point and medium for the expression of nationalistic reactions to the increasing numbers of loan-words in Japanese, and hence its subliminal influence and image as a defender of the purity of the Japanese language, cannot entirely be dismissed. This is perhaps somewhat ironic considering that its linguistic influences were never as far-reaching as those of Buddhism and that its very emergence as a named entity was very much dependent on the tools provided by Japan's cultural borrowings from Chinese culture.

Shklovsky, Viktor Borisovich (1893–1984)

S Archaimbault, Université Paris, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Viktor Borisovich Shklovskij (Shklovsky) was born in 1893. Both a writer and a critic, he came to be known in 1913 thanks to his conference on the 'Role of Futurism in Language History.' In the article 'The resurrection of words' (1914), he advocated the need for a poetical reflection based on the general laws of language evolution. With this article, Shklovskij started a polemical debate in absentia with A. Potebnja, who drew his dynamic conception of language from Humboldt. The word, along with its content (a logical, lexical meaning), also has an internal form (a concrete image) that motivates its sound. For Potebnja, the image stands for the creative energy of language, but it progressively erodes as the internal form fades away. The erosion process underlies the passage from poetry to prose. Shklovskij started from this observation to posit the need for a renewal of language and to ground the futurists' attempts. In passing, he also criticized Potebnja for not paying attention to the external form. Moreover, he stated the necessity of positing the existence of a 'prosaic language' and a 'poetic language,' which obey different laws. Later on, he elaborated on such criticisms, and more precisely on the conceptual ambiguity linked to images, in his 1917 article 'Art as a process.'

Shklovsky, Viktor Borisovich (1893–1984)

S Archaimbault, Université Paris, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Viktor Borisovich Shklovskij (Shklovsky) was born in 1893. Both a writer and a critic, he came to be known in 1913 thanks to his conference on the 'Role of Futurism in Language History.' In the article 'The resurrection of words' (1914), he advocated the need for a poetical reflection based on the general laws of language evolution. With this article, Shklovskij started a polemical debate in absentia with A. Potebnja, who drew his dynamic conception of language from Humboldt. The word, along with its content (a logical, lexical meaning), also has an internal form (a concrete image) that motivates its sound. For Potebnja, the image stands for the creative energy of language, but it progressively erodes as the internal form fades away. The erosion process underlies the passage from poetry to prose. Shklovskij started from this observation to posit the need for a renewal of language and to ground the futurists' attempts. In passing, he also criticized Potebnja for not paying attention to the external form. Moreover, he stated the necessity of positing the existence of a 'prosaic language' and a 'poetic language,' which obey different laws. Later on, he elaborated on such criticisms, and more precisely on the conceptual ambiguity linked to images, in his 1917 article 'Art as a process.'

The dialogue between the poetic vanguard and the general linguistic reflection was triggered by Jan Baudoin de Courtenay, who was interested in the 'transmental language' (*zaum*) of the futurists and who accepted having public discussions with Shklovskij about futurism. Baudoin made him meet several of his young disciples, such as Lev Jakubinskij and Lev Polivanov.

Shklovskij was one of the bold young men who, in 1916, launched the review *Pétrograd*, published and funded by Osip Brik, and who created the Society for the Study of the Poetical Language at the beginning of 1917 in Pétrograd. The Society thus integrated the Moscow Linguistic Circle created by Roman Jakobson. Personalities such as J. Tynjanov, B. Ejkhenbaum, and so forth soon joined this new circle, which was to be known under the acronym OPOIAZ (**O**bshchestvo izuchenija **PO**eticheskago **JAZ**yka) and remain associated with the Russian formalist school.

Viktor Shklovskij played a major role in the identification among writers – notably L. Tolstoï – of a process of 'defamiliarization,' 'distanciation,' or 'estrangement,' *ostranenie*. It means that for a thing to acquire an artistic value it must be cut off from its usual associations. Shklovskij studied the unfolding of this process in *War and peace*: He tried to show that Tolstoï does not name things by their habitual names but pretends that he sees them for the first time. He regarded that as a rehabilitation of sensation at the expense of knowledge.

He also aimed at defining the laws of the construction of the narrative subject. His examples are drawn from a very large and very varied corpus of Russian or foreign prose, poetry, folklore, theatre, which all rely on a general law, governed by 'gradation' and 'delay.'

During his exile in Berlin in 1922 to 1923, he published 'The horse ride,' a miscellany of articles previously published in Russia and headed by a text that may be the key to his entire work. The horse or horse rider rides sideways, because it is a convention of art, but also because he is not free – there is no direct way for him.

Even if Viktor Shklovskij is mainly known for his activity in the 1920s, he remained a versatile and prolific writer and critic, whose passion was literature as well as cinema, for which he wrote many a scenario. He was an eccentric and indefinable man, and he also appeared once in a while as a literary character, in works such as *The white guard* by M. Bulgakov (1924) and *Skandalist* by V. Kaverin (1928).

Several writers, such as Boris Ejkhenbaum and Mikhail Zoshchenko, have praised his writing, thanking him for shortening the sentences and 'airing' his articles. As for readers, they remember the vivid impression of a friendly dialogue, or even asides, with the author: addresses, direct or subliminal messages, private jokes, apologies for the complexity of the composition of a book, and so forth. As an example, we will quote the last sentences of his miscellany of selected works published in 1983, one year before he died:

> Hail to you, reader. Read this book at home, read it in your garden, if your head is not spinning when you look at the trees in the sun spots.

Shona

D Odden, The Ohio State University, Columbus, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Shona is a member of the Bantu language family, S10 in the Guthrie classification, having roughly 7 000 000 speakers in Botswana, Malawi, Mozambique, and Zambia, with the majority of speakers in Zimbabwe. Shona is the dominant African language of Zimbabwe; as one of the major languages of southern Africa, the speaker population is comparable to that of Zulu and Xhosa. Shona is also a literary language, with a considerable literature having developed since the 1950s. The main dialects of Shona are Karanga, Korekore, Manyika, and Zezuru; Zezuru forms the basis of the

standard language. Ndau and Kalanga are closely related and might be considered to be highly divergent dialects or closely related but separate languages: in this article, they will not be treated as Shona dialects. The main linguistic reference works for Shona are the reference grammars of Fortune (1955, 1980) an extensive dictionary indicating tone and dialectal properties (Hannan, 1984), and *Duramazwi Guru reChiShona*, which is a major Shona monolingual dictionary.

With 5 vowels and minimally 32 uncontroversial consonants, Shona has somewhat more than the usual complement of consonants for Bantu languages. The consonantal system includes a contrast between the labiodental fricative [v], spelled *vh*, and a bilabial semi-approximant [β], spelled *v*, as well as a labiodental flap [v̌] found in some ideophones and reported in a few nouns, as well as a contrast [b, d] vs. [ɓ, ɗ]. The most well-known phonetic oddity of Shona is a set of 'whistling fricatives,' a set of retracted alveolar fricatives and affricates articulated between [s] and [š] (with which they contrast), produced with a degree of lip protrusion but not full rounding: these sounds, for which the International Phonetic Alphabet (IPA) lacks symbols, are spelled *sv*, *zv*, *tsv*, *dzv*. In some dialects, especially Manyika, the labial constriction is so extreme that a stop closure is formed. In addition, the language has a series of prenasalized consonants of nasal plus consonant sequences [mb], etc., and morphophonemic consonant plus *w* sequences pronounced with various degrees of velarization according to dialect, so that /tw/ may be phonetically [txw] or [tkw] with unrounding after labials, and /pw/ may be [px] or [pk].

Shona is a tone language, but extensive tonal data is available only for the Karanga and Zezuru dialects (see Fivaz (1970) and Fortune (1980) for tone-marked paradigms of Zezuru, Myers (1987) for analysis, and Odden (1981) for Karanga). Differences in the tonal morphophonemics of different Shona dialects are significant, and are comparable to tonal differences across Makonde dialects or the so-called Luhya languages. One characteristic of Shona tonology is a panoply of dissimilative H-tone lowering and rightward spreading processes, which are subject to a variety of morphosyntactic conditions. Tone-melodic inflectional patterns also play a role in marking tense aspect and clause type, providing the sole distinction between forms such as (Karanga) *akarima* 'then he plowed', *ákáríma* 'he plowed (yesterday)', and *ákárimá* 'he having plowed'.

Shona exhibits typical structural properties of Bantu languages. It has a rich system of 19 noun classes marked on nouns by prefixes that encode singular/plural distinctions as well as semantic properties (such as diminutives and augmentatives), with all of the proto-Bantu noun classes represented, except **gʊ-* – class 19 **pi-* is represented in the Karanga dialect by the diminutive *svi-*. Noun stems can thus appear in a number of classes, the choice of class marking semantic differences, e.g., *mu-kómaná* 'boy', *gómaná* 'huge boy', *chi-kómaná* 'short boy', *ka-kómaná* 'tiny sickly boy', *ru-kómaná* 'thin boy', and *svi-kómaná* 'little boy'. The Bantu class 5 prefix **li-* is itself phonologically null in Shona, and voicing of a stem-initial stop replaces an overt prefix in [ɓáŋgá] 'knife' ~ [ma-páŋgá] 'knives', [ɗéndé] 'gourd' ~ [ma-téndé] 'gourds', [guɗo] 'baboon' ~ [ma-kuɗo] 'baboons', [ǰékó] 'sickle' ~ [ma-čékó] 'sickles': observe that the voiced correspondents of *p*, *t* are the implosives [ɓ, ɗ], not [b, d].

Verb morphology is particularly rich. Stems are composed of a root plus a number of fully and partially productive derivational suffixes marking causative (*-is-*), applicative (*-ir-*), reciprocal (*-an-*), passive (*-w-*), intensive (*-is-*, *-isis-*), reversive (*-Vnur-*), and stative (*-ik-*), as well as reduplication for frequent actions. Pronominal markers include encoding of objects, subjects, and relative clause heads for each of the noun classes. Tense-aspect marking indicates past, present, future, persistive, potential, subjunctive, imperative, hortative, and numerous other distinctions, as well as corresponding negative and subordinate clause forms. The word-formation potential of Shona reaches astronomical levels due to a series of *Aktionsart* prefixes such as *-do-* 'willingly', *-ndo-* 'go', *-zo-* 'hypothetical, remote', *-garo-* 'always', *-nyatso-* 'do well', and *-raro-* 'at night'; thus *ndichá-dó-rima* 'I will gladly plow', *ndichá-zó-rima* 'I will plow in the remote future', and *ndichá-nyatsó-rima* 'I will plow well'. These prefixes can be combined and permuted, so that *ndichá-zó-ndó-ráro-rima* 'I will perhaps go plow at night' can also be rendered as *ndichá-ndó-zó-ráro-rima*.

Shona syntax is typical for a Bantu language. Noun phrases are fairly strictly head initial, with noun class agreement governed by the head noun (*vána va-kúrú va-virí vá-no* [children big two these] 'these two big children'), though some determiners may be put before the head noun (*iri bángá* [this knife]). Derivational verbal extensions such as the causative and applicative allow a clause to have multiple bare objects, e.g., *ákáríma munda* 'he plowed the field', *ákárímisa Fárái munda* 'he made Farai plow the field', and *ákárímira munhu munda* 'he plowed the field for the person'. Locative noun phrases can ostensibly function as subjects via inversion (*mu-mbá mw-ákárára vaná* [in-house loc-slept children] the children slept in the house') or passivization (*mu-mbá mw-ákafámb-w-á naFárai* [in-house

loc-walk-passive by-Farai] 'in the house was walked by Farai').

Roger Shuy is Distinguished Research Professor of Linguistics, Emeritus at Georgetown University (Washington, DC, USA). He spent over three decades at Georgetown University and served jointly at the Center for Applied Linguistics from 1967 to 1985.

Shuy earned a B.A. in English from Wheaton College and went on to study at Kent State University. He received his Ph.D. in English and Linguistics from Case Western Reserve University in 1962.

Shuy has conducted research in the area of sociolinguistics. His early interests were in social dialects and the relation of linguistic diversity to language learning. He is a social advocate and has worked to apply linguistics to social concerns. Shuy was the President of the American Association for Applied Linguistics (AAAL) from 1978 to 1980. He was honored in 1999 by AAAL with a Distinguished Scholarship and Service Award. A festschrift called *Language in action: New studies of language in society* was written in his honor in 2000.

He has been at the forefront of the emerging field of forensic linguistics, the application of linguistics to criminal law. Shuy has consulted on over 500 court cases and has testified as an expert witness in over 50 criminal and civil trials, including the high profile case involving auto executive John DeLorean. He testified before the U.S. Senate and the U.S. House of Representatives in the impeachment trials of Senator Harrison A. Williams and others involved in the FBI Abscam operation. Shuy also served as a consultant on the Unibomber case and received an award from the FBI for his service. He has written several influential books in the area of forensic linguistics, including *Language crimes* (1993) and *The language of confession, interrogation, and deception* (1998). He has also written about language use in corporate advertising in the book *Linguistic battles in trademark disputes* (2002). He is currently the President of Roger W. Shuy, Inc. and continues to do linguistic research and consulting from his office in Montana.

Sibata, Takesi (b. 1918)

Y Nagashima, Gakushuin University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Takesi Sibata was born in Nagoya, Japan on July 14, 1918. He graduated from the University of Tokyo with an M.A. in 1942 and received his D.Litt. in 1969 from the same university. He was a professor at Tokyo University of Foreign Studies from 1964 to 1968 and then became professor at his alma mater in 1968, where he was chairman of the Department of Linguistics from 1969 to 1978 and remained there until his retirement in 1979. He received the title of Professor Emeritus of the University of Tokyo in 1987.

His major fields include Turkish, linguistic geography, sociolinguistics, onomastics, and Japanese lexicology. He worked for the National Institute for Japanese Language Research from 1949 to 1964. His major work there was the preparation of the massive *Nihon Gengo Chizu* (*Japanese Linguistic Atlas*), which was published in six volumes from 1966 to 1975. Parallel with this work, he carried out other intensive fieldwork on linguistic geography in Itoigwa area, Niigata Prefecture, with several collaborators. The unique feature of the survey was a microscopic survey of every inhabitant in the area. Through the analysis of the survey, he developed an original method of linguistic geography, the outline of which can be seen in Sibata (1969). The publication of the whole work was completed in the form of Sibata (1988–1995).

In the field of sociolinguistics, he put forward a new point of view from which to survey people's verbal behavior in every aspect of everyday life: when and how people speak, listen, write, read, and keep silent. This whole complex of activities is called in Japanese *gengo seikatsu*, which literally means 'verbal life'.

Sibata has also contributed greatly to the development of Japanese lexicology and lexicography. He produced three volumes on the semantic analysis of basic Japanese words with other colleagues. He is a co-editor of several Japanese dictionaries, and was especially responsible for the description of word accents and the meaning of loanwords. Since 1966, he has been a member of the Committee for Japanese for Broadcasting at Nihon Hoso Kyokai (Japanese Broadcasting Corporation) and a member of the government committee for Japanese language policy. He also served as a member of the Japan Academic Association from 1988 to 1994.

Sibawayhi (8th Century A.D.)

S I Sara, Georgetown University, Washington, D.C., USA

© 2006 Elsevier Ltd. All rights reserved.

Sībawayh is ʔabu Bišr ʔibn ʕuΘmān ʔibn Qanbar Sībawayh. He is an 8th century linguist (140?–180 H/757–796 A.D.), who wrote the first grammar of Arabic. He is known simply as Sībawayh. He was born in Baydˤāʔ, in the province of Shiraz, in southwestern Persia. From Persia, his family migrated to Basrah, and Sībawayh studied first under Qurʔanic teachers, but due to some linguistic embarrassment, he ended up with ʕabdu ʕal-Raħmān ʔal-Khalīl ʔibn ʔaħmad ʔal-Farāhīdī (100–175 H/719–791 A.D.). In this new environment, he excelled in linguistic matters and would become the person both to set down the principles of Arabic grammar and to compose the first grammar of Arabic in a manner that has not been surpassed. His was the first full treatment of Arabic; it is both comprehensive and thorough. Sībawayh is to Arabic grammar what Panini (c. 400 B.C.) is to Sanskrit grammar – they are both of equal prestige in their respective cultures.

Sībawayh wrote only one book, called *ʔal-kitāb* 'The book'; it included, in the order of appearance, the general norms of grammatical analysis, syntax, and morphology, and it concluded with the phonetics of Arabic. Within its ~950 pages of text, the grammar is composed of 571 chapters. The subject matter of analysis is the Arabic used in the Qurʔān, the Arabic used by the pre-Islamic and Islamic poets, but rarely contemporaries, and the Arabic of speakers whose Arabic was considered acceptable, which often meant representative of the known tribes across the peninsula from Hijaz in the West to Tamiym and Basrah in the East. All were held in equal respect, and no datum was considered more correct than the other because it occurred in the Qurʔān, was spoken by a famous poet, or came from a prestigious tribe. Each piece of data was acceptable in form and content because it was in use by the Arabs, and it was patterned according to their usage.

'The book,' with all its rich linguistic analyses, is a treasure of linguistic lore. It summarizes the state of linguistic studies of Arabic at the time of Sībawayh. It culls from the sayings of the ancient grammarians what was known at the time, it quotes abundantly from his teachers and their teachers on the testimony of respected authorities, and even though it is a synchronic statement about the structure of the Arabic spoken at the time of Sībawayh, the account it provides of the previous generation(s) of linguists gives the book a historical dimension and depth. One can gauge the weight of one person versus another by the number of citations or references the author gives him or her. For example, Al-Khalīl is mentioned 608 times, Yuwnus 217 times, ʔibn ʔabi ʔisħāq 7 times, and ʔibn Marwān once. This goes also for the poets and tribes listed in the book. This in no way implies that Sībawayh was a mere chronicler of opinions; rather, he was an original linguistic thinker who systematized and formalized the complex Arabic grammar in an unprecedented manner. Compare his phonetics (cf. Table 1) with those of Al-Khalīl, his teacher.

The book begins by dividing the Arabic *kalimu* 'words' into three classes: *ʔism* 'name/noun', *fiʕl* 'action/verb', and *ħarf* 'particle'. The particles are invariable, but the *ʔism* 'name/noun' and *fiʕl* 'action/verb' have variable endings. To explain the variations in the forms of Arabic, called *ʔi ʕrāb* 'desinence',

Table 1 Sībawayh's phonetic table

Lower perimeters	*Muxrag 'exit'*	*Upper perimeters*
1. Throat: farthest section	ʔ, h, A ʔ/ء, ه, ا	1. Throat: farthest section
2. Throat: mid section	ʕ, ħ, ع, ح	2. Throat: mid section
3. Throat: closest to oral cavity	ɣ, x / غ, خ	3. Throat: closest to oral cavity
4. Tongue: farthest section	G / ق	4. Palate: farthest section
5. Tongue: lower than [G]	k/ك	5. Palate: pre-farthest section
6. Tongue: mid section	g,š,y/ج,ش,ي	6. Palate: mid section
7. Tongue: beginning of edge	dˤ /ض	7. Palate: molar section
8. Tongue: closest edge to tip	l/ل	8. Palate: above pre-molars, canines and incisors
9. Tongue: tip	n/ن	9. Palate: above the incisors
10. Tongue: slightly inner surface of the tongue	r/ ر	10. Palate: above the incisors
11. Tongue: tip	z,s,sˤ/ زسص	11. Palate: slightly above the incisors
12. Tongue: tip	tˤ ,d,t/ط, د, ت	12. Palate: base of incisors
13. Tongue: tip	ðˤ ,ð,θ / ظ, ذ, ث	13. Teeth: tip of incisors
14. Lip: inner surface of the lower lip	f/ف	14. Teeth: tip of the upper teeth
15. Lip: lower	b,m,w/ ب, م, و	15. Lip: upper
16. Nostrils: nasal cavity	light [n]/ ن	16. Nostrils: nasal cavity

Sībawayh proposed the concept of *ʕāmil / ʕawāmil* 'operator/s', that is, variation was motivated, not random. For example, *Hāða zaydun* 'this is Zayd'; *Raʔaytu zaydan* 'I saw Zayd'; *Marartu bi-zaydin* 'I passed by Zayd'. The variation [-un, -an, -in] in Zayd indicates its desinence due to syntactic factors/operations. It is estimated that more than 9000 sentences, 1000 lines of poetry, and 400 verses from the Qurʔān, and countless morphological structures are discussed and analyzed in the book. Sībawayh and Al-Khalīl are responsible for the multitude of technical terms and the intellectual structure of the discipline of Arabic linguistics.

Sierra Leone: Language Situation

C N Fyle

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 7, p. 3883, © 1994, Elsevier Ltd.

Sierra Leone has a population of some 4 million people over a land area of 71 740 square kilometers, giving a density of some 55 persons per square kilometer on the average. There are 18 languages, distributed as shown in **Table 1**. (The percentages in **Table 1** are derived from the 1963 census figures. It is unlikely the picture has changed significantly.)

Eight of the languages: Susu, Yalunka, Mandingo (Maninka, Kankan), Kono, Vai, Loko, Mende, and Kuranko, belong to the Mande language group, which stretches from Senegal to Sudan. Seven others are Niger–Congo languages within the African fragmentation belt, namely: Temne (Themne), Kisi, Krim, and Gola belonging to the Mel group, as well as Fula (Pulaar), Kru (Klao), and Limba. Sherbro and Galinas also may belong here but their affinities are unknown. Krio is an English-related creole language that has strong affinities with Aku, Fernandino (Bubu), and Weskos in the Gambia, Equatorial Guinea, and Cameroon respectively.

Krio is the lingua franca of Sierra Leone but this language has only recently received recognition as a language in its own right. Two other nonindigenous languages exist. Arabic is a language of religion but also of some business at grassroots level (*see* **Arabic**). English is the official and international language of government, business and administration, broadcasting and journalism, and education.

The population density figure, as well as a century-old tradition of social mobility, indicate that there is a fair amount of language contact, resulting in widespread bilingualism/multilingualism. The order is that

Table I Percentage of speakers by language

Language	*% of population using language*	*Language*	*% of population using language*
Mende	29.9	Mandingo	2.3
Temne	24.4	Kisi	2.2
Limba	8.1	Krio	1.9
Kono	4.6	Yalunka	0.7
Kuranko	3.6	Krim	0.4
Sherbro	3.3	Vai	0.2
Susu	3.0	Gola	0.2
Fula	3.0	Kru	0.2
Loko	2.9	Galinas	0.1

Sībawayh proposed the concept of *ʕāmil / ʕawāmil* 'operator/s', that is, variation was motivated, not random. For example, *Hāða zaydun* 'this is Zayd'; *Raʔaytu zaydan* 'I saw Zayd'; *Marartu bi-zaydin* 'I passed by Zayd'. Sierra Leone: Language Situation

C N Fyle

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 7, p. 3883, © 1994, Elsevier Ltd.

Sierra Leone has a population of some 4 million people over a land area of 71 740 square kilometers, giving a density of some 55 persons per square kilometer on the average. There are 18 languages, distributed as shown in Table 1. (The percentages in Table 1 are derived from the 1963 census figures. It is unlikely the picture has changed significantly.)

Eight of the languages: Susu, Yalunka, Mandingo (Maninka, Kankan), Kono, Vai, Loko, Mende, and Kuranko, belong to the Mande language group, which stretches from Senegal to Sudan. Seven others are Niger–Congo languages within the African fragmentation belt, namely: Temne (Themne), Kisi, Krim, and Gola belonging to the Mel group, as well as Fula (Pulaar), Kru (Klao), and Limba. Sherbro and Galinas also may belong here but their affinities are unknown. Krio is an English-related creole language that has strong affinities with Aku, Fernandino (Bubu), and Weskos in the Gambia, Equatorial Guinea, and Cameroon respectively.

Krio is the lingua franca of Sierra Leone but this language has only recently received recognition as a language in its own right. Two other nonindigenous languages exist. Arabic is a language of religion but also of some business at grassroots level (*see* **Arabic**). English is the official and international language of government, business and administration, broadcasting and journalism, and education.

The population density figure, as well as a century-old tradition of social mobility, indicate that there is a fair amount of language contact, resulting in widespread bilingualism/multilingualism. The order is that

Table I Percentage of speakers by language

Language	*% of population using language*	*Language*	*% of population using language*
Mende	29.9	Mandingo	2.3
Temne	24.4	Kisi	2.2
Limba	8.1	Krio	1.9
Kono	4.6	Yalunka	0.7
Kuranko	3.6	Krim	0.4
Sherbro	3.3	Vai	0.2
Susu	3.0	Gola	0.2
Fula	3.0	Kru	0.2
Loko	2.9	Galinas	0.1

of English (for the educated), Krio, Mende or Temne (the largest languages), then the mother tongue if different. Incidentally, this pattern also represents the hierarchy of language status.

Even so, and perhaps because of a much older tradition of group consciousness, dialectal differences tend to be marked especially for the larger languages. Thus Mende has at least six distinct dialects (Ko, Sewama, Komboya, Kpa, Sherbro, and Wanjama Mende), Temne has three (Konkay, Yoni, and Gbembeli Temne), and Limba has four (Safroko, Wara-wara, Tonko, and Biriwa Limba). The comparatively large number of the languages themselves, as well as the tendency towards dialectal preservation, have been factors in hindering language development in Sierra Leone. Another factor has been the status of English as an elitist language.

Linguistic studies began early in the 20th century with Koelle's *Polyglotta Africana* (*see* **Koelle, Sigismund Wilhelm (1823–1902)**) but slowed drastically, so that over the years language development work has depended upon the isolated and unsystematic efforts of only some foreign scholars – the small linguistics department of the university is of very recent creation. Consequently most of the languages have not been properly described. Thus, for example, attempts since the mid to late 1970s to use Mende, Temne, Krio, and Limba as instructional media in primary education, through the government's Sierra Leone Indigenous Languages Project, have so far not succeeded, very largely because of a lack of the necessary linguistic backup materials – for example, a dictionary and a grammar of Limba – are not even available. However, recommended orthographies are available for nine of the languages, and these are used in literacy materials production and programs.

Illiteracy remains widespread, despite efforts since the early 1960s to eradicate it. The rates are 69.3% men, 88.7% women, and overall 79.3%. Little printed literature is available in the languages; and the Bunumbu Press, the sole rural press that used to publish literacy and postliteracy materials as well as a rural newspaper in eight languages, has been dormant, though there are plans for its revival during the 1990s. The government is begining to place much emphasis on universal literacy and the use of national languages in education.

The teaching of French (and French only), as a second language in addition to English, continues to be encouraged at the national university and in all secondary schools.

Sievers, Eduard (1850–1932)

E Einhauser, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

Together with Hermann Paul and Wilhelm Braune, Eduard Sievers was one of the Germanists who, in connection with some Indo-Europeanists, can be seen as the central group of the so-called Neogrammarians. In comparison with Paul and Braune he certainly was the most outstanding character. Even though he was much more interested in the natural sciences, out of economic reasons he decided to study philologies and managed to get his final degree when he was only 19 years old. One year later he was already a professor in Jena. Due to his reputation and probably also due to the fact that he could speak English fluently (which was quite unusual at that time) he was offered a chair at Harvard University, in Cambridge, Massachusetts, in 1881. Sievers declined the offer due to personal reasons and taught in Tübingen and Halle for several years instead, until finally he was offered a chair at the University of Leipzig and so returned to the place where he started his career. There he died in 1932.

Looking at his numerous publications there is no doubt that his book *Grundzüge der Lautphysiologie* (1876) was of great influence on the development of

of English (for the educated), Krio, Mende or Temne (the largest languages), then the mother tongue if different. Incidentally, this pattern also represents the hierarchy of language status.

Even so, and perhaps because of a much older tradition of group consciousness, dialectal differences tend to be marked especially for the larger languages. Thus Mende has at least six distinct dialects (Ko, Sewama, Komboya, Kpa, Sherbro, and Wanjama Mende), Temne has three (Konkay, Yoni, and Gbembeli Temne), and Limba has four (Safroko, Wara-wara, Tonko, and Biriwa Limba). The comparatively large number of the languages themselves, as well as the tendency towards dialectal preservation, have been factors in hindering language development in Sierra Leone. Another factor has been the status of English as an elitist language.

Linguistic studies began early in the 20th century with Koelle's *Polyglotta Africana* (*see* **Koelle, Sigismund Wilhelm (1823–1902)**) but slowed drastically, so that over the years language development work has depended upon the isolated and unsystematic efforts of only some foreign scholars – the small linguistics department of the university is of very recent creation. Sievers, Eduard (1850–1932)

E Einhauser, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

Together with Hermann Paul and Wilhelm Braune, Eduard Sievers was one of the Germanists who, in connection with some Indo-Europeanists, can be seen as the central group of the so-called Neogrammarians. In comparison with Paul and Braune he certainly was the most outstanding character. Even though he was much more interested in the natural sciences, out of economic reasons he decided to study philologies and managed to get his final degree when he was only 19 years old. One year later he was already a professor in Jena. Due to his reputation and probably also due to the fact that he could speak English fluently (which was quite unusual at that time) he was offered a chair at Harvard University, in Cambridge, Massachusetts, in 1881. Sievers declined the offer due to personal reasons and taught in Tübingen and Halle for several years instead, until finally he was offered a chair at the University of Leipzig and so returned to the place where he started his career. There he died in 1932.

Looking at his numerous publications there is no doubt that his book *Grundzüge der Lautphysiologie* (1876) was of great influence on the development of

the phonetical studies at that time. When the second edition – revised under the influence of the works of Henry Sweet and Johan Storm – was published only 5 years later, the title was changed accordingly: *Grundzüge der Phonetik*.

The importance of Sievers for this scientific branch was only recently emphasized once more by Christine Römer (2001). But whereas Peter Ganz (1978) and L.R. Sinder (1982) were convinced that Sievers already had an idea of the concept of phonemes, even though he did not introduce a special term for it, Römer believed Sievers to be a precursor of sociolinguistics rather than of phonology: "Sievers was interested in anthropological-social aspects, which from the point of view of de Saussure did not belong to the center of linguistics ..." (Römer, 2001: 123). This may be true for his later development, but at least in the first half of his scientific life his point of view was rather close to that which de Saussure pronounced later on. So in his first edition of the *Grundzüge* Sievers postulated that for the linguist "not the single sound is of value, but the soundsystems of the single language units, their relationship and their gradual shift" (Sievers, 1876: 2). Of course—differing from de Saussure—the historical aspect still functions as a kind of frame for the analysis of sound systems; nevertheless, this passage shows that Sievers was not interested in the analysis of isolated elements (see also Schneider, 2001: 180) and therefore was far from being the purely positivistic linguist, to which the Neogrammarians often were (and sometimes still are) presented.

This can be confirmed further by the fact that Sievers was well aware of the importance of the context. He therefore proposed to start with the sentence, when analyzing the sound system of a language, "because the sentence alone is the object which occurs in spoken language and can be observed directly" (Sievers, 1893: 7). Considering his rather modern definition of sentences (Sievers, 1893: 211) one can say that some of his views were rather progressive for its time.

Besides his *Grundzüge* it was namely his *Angelsächsiche Grammatik* (1882) that was widely appreciated and soon translated into English (1885) (the *Abriss*, i.e., the short version, was in print until 1963!). The grammar was quite an improvement in comparison to other publications on Old English because Sievers's comments were not based on poetic texts alone but also on prose fiction. It should also be mentioned that early in his career Sievers presented himself not only as a linguist but also as a philologist in the traditional sense of the word, e.g., he produced critical editions of the *Tatian* (1872), the *Murbacher Hymnen* (1874), and the *Heliand* (1878).

Later on his scientific focus changed completely. The turning point probably was his work on the *Altgermanische Metrik* (1893). Here for the first time he used a kind of experimental-aesthetic method, based on the conviction that the hearer is able to reconstruct the original rhythmical structure of a text as intended by the author. Sievers was convinced that this method, which he explained in more detail in 1912 in his *Rhythmisch-melodische Studien*, was an appropriate instrument for critical text editions. Most scientists would not accept Sievers's so-called *Schallanalyse* ('analysis of sound'); however, they were not able to dissuade him from his conviction. He concentrated on the further development of the method during the last decades of his life. But since he did not manage to supply his experiments with a sufficient theoretical fundament, the *Schallanalyse* fell into oblivion after his death (for details, see Frings, 1933; Ungeheuer, 1964).

Most probably Sievers will mainly be remembered as the author of the *Angelsächsische Grammatik* and especially of the *Grundzüge*, which, with respect to its influence, Kurt R. Jankowsky compared with Hermann Paul's *Prinzipien der Sprachgeschichte*. They "proved to be most powerful and influential guidelines for the reorientation of linguistic research in that both monographs offered an abundance of detailed methodological reflection unavailable through any other existing publication" (Jankowsky, 2001: 1357).

Siger de Courtrai (d. 1341)

L Kaczmarek, Borgholzhausen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Siger of Courtrai (latinized as Sigerus de Cortraco/Curtrarco, and named Zeger van Kortrijk in Flemish) was born c. 1283 in Gullegem (then Ghueldeghem) near Kortrijk/Courtrai, Flanders, Belgium. Since c. 1309 he had taught as *Magister artium regens* in Paris, where in 1310 he became a *socius*, and in 1315 the *procurator* of the Sorbonne, at a time when his colleague Radulphus Brito was its provisor. In 1308, he is mentioned as dean of the chapter of Notre-Dame de Courtrai and remained in that position until 1327. He died in Paris on May 30, 1341.

Siger composed his logicolinguistic works after 1300, probably between 1310 and 1320. His widely known *Summa modorum significandi* (edited in Wallerand, 1913: 93–125, reedited in Pinborg, 1977: 1–40), though incomplete, made him an important figure in the endeavors of the medieval Modistic linguists, while expanding on Priscian's *Institutiones grammaticae*, to construct a speculative grammar on the basic notions of *modus essendi, modus intelligendi*, and *modus significandi*. As a philosopher, this later-generation Modist drew on Thomas Aquinas and Albert the Great, whereas he was reluctant with Radulphus Brito's new ideas. Previous to the *Summa*, Siger wrote *Sophismata* (4 of them edited in Wallerand, 1913: 129–165; 7 in Pinborg, 1977: 41–95; cf. Kann, 1999), and even earlier he had commented on Aristotle's *Categories*, on *On interpretation* (edited in Verhaak, 1964), on the *Prior analytics* (edited in Wallerand, 1913: 1–75), on Porphyry's *Isagoge* and on *De sex principiis*. He also left us fragments of *Fallaciae* (edited in Wallerand, 1913: 79–90), where he also mentions his *Ars obligatoria*, as yet unidentified. A tract on *Impossibilia* is also attributed to him.

Sign Language: Acquisition

R I Mayberry and B Squires, University of California, San Diego, CA, USA and McGill University, QC, Canada

© 2006 Elsevier Ltd. All rights reserved.

Sign languages are expressed with the hands, arms, and face and are understood through the eyes. Sign languages have evolved within communities of individuals who are deaf, and the children of these communities acquire sign as a first language. Like all languages, sign languages have linguistic rules for how words, sentences, and discourse are structured. Thus, all sign languages have a lexicon, grammatical and derivational morphology, phonology, syntax, and semantics. We focus here on sign language acquisition begun in infancy, as is typical for spoken language acquisition.

Sign language acquisition has been studied in several languages, including American Sign Language (ASL), Australian Sign Language (Auslan), British Sign Language (BSL), Danish Sign Language (DSL), French Sign Language (LSF), Italian Sign Language (LIS), Japanese Sign Language (JSL), Sign Language of The Netherlands (SLN), and Quebec Sign Language (LSQ). Research suggests that the developmental path from first words and combinations to sentence structure and discourse is similar across sign languages, although it is important to remember that the linguistic details vary from sign language to sign language (see **Table 1**). Sign language research reveals that the child's discovery of the units and rules of grammar is an abstract process that transcends sensory-motor modality.

Infant-directed sign language attracts and holds babies' attention more than adult-directed sign does, even when babies have never seen sign before. Infant-directed sign is slower, with larger movement trajectories, and tends to have more repetitions, compared to adult-directed sign (Masataka, 1996). Some elements of infant-directed sign are ungrammatical for adult signers but are modified in infant-directed sign to accommodate the visual needs of babies. For example, adults will displace signs away from their bodies to sign within the baby's visual field until the infant is about 20 months old, the time at which infants look automatically at the visual linguistic input source. Children must learn where to look to 'see' language, a task unique to sign language acquisition (Harris and Mohay, 1997; Holzrichter and Meier, 2000). Another modification in infant-directed sign involves facial expression. In adult sign language, facial expression has two functions, the affective function, which is universal to humans, and the linguistic function, which is unique to sign languages. In infant-directed sign, adults use only affective facial expression. When children have acquired signs for some facial linguistic markers, around 24 months of age, adults can begin to add more linguistic facial expressions to their infant-directed sign (Reilly *et al.*, 1991; Reilly, 1996).

Infants who experience sign language babble with their hands. Manual babble occurs around the same age as vocal babble, from 6 to 12 months. Manual babble consists of a reduced set of phonological parameters found in the sign language input and follows the syllabic organization of sign languages, especially with respect to rhythmic timing. The handshapes most commonly observed in manual babbling are: [5] (relaxed hand), [A] (fist), [0] (including baby O), and [G] (index point). These handshapes are used with more repetitious movements than they are in the adult model, and movements such as opening and closing the handshape, raising and lowering the hands or arms, and movement toward the body are common. The location (or place) parameter of manual babbling seems to be idiosyncratic; for example, some infants babble in neutral space in front of the body, while others babble mostly on the head or face (Petitto and Marentette, 1991).

The transition from manual babbling to first words occurs around 10 months of age (with large individual variation). Manual babble and communicative pointing decline just before the appearance of the first sign (Petitto, 1987). First signs have been reported from as early as 8 months to as late as 16 months. The first 10 signs are produced around 12 months of age, and the first 50 signs emerge at 24 months and older (Anderson and Reilly, 2002). Children inevitably make signing errors; the phonological parameters used most frequently in manual babble tend to be the most common substitution errors in early sign (see **Figure 1**). The sign parameters

Sign Language: Acquisition

R I Mayberry and B Squires, University of California, San Diego, CA, USA and McGill University, QC, Canada

Sign languages are expressed with the hands, arms, and face and are understood through the eyes. Sign languages have evolved within communities of individuals who are deaf, and the children of these communities acquire sign as a first language. Like all languages, sign languages have linguistic rules for how words, sentences, and discourse are structured. Thus, all sign languages have a lexicon, grammatical and derivational morphology, phonology, syntax, and semantics. We focus here on sign language acquisition begun in infancy, as is typical for spoken language acquisition.

Sign language acquisition has been studied in several languages, including American Sign Language (ASL), Australian Sign Language (Auslan), British Sign Language (BSL), Danish Sign Language (DSL), French Sign Language (LSF), Italian Sign Language (LIS), Japanese Sign Language (JSL), Sign Language of The Netherlands (SLN), and Quebec Sign Language (LSQ). Research suggests that the developmental path from first words and combinations to sentence structure and discourse is similar across sign languages, although it is important to remember that the linguistic details vary from sign language to sign language (see Table 1). Sign language research reveals that the child's discovery of the units and rules of grammar is an abstract process that transcends sensory-motor modality.

Infant-directed sign language attracts and holds babies' attention more than adult-directed sign does, even when babies have never seen sign before. Infant-directed sign is slower, with larger movement trajectories, and tends to have more repetitions, compared to adult-directed sign (Masataka, 1996). Some elements of infant-directed sign are ungrammatical for adult signers but are modified in infant-directed sign to accommodate the visual needs of babies. For example, adults will displace signs away from their bodies to sign within the baby's visual field until the infant is about 20 months old, the time at which infants look automatically at the visual linguistic input source. Children must learn where to look to 'see' language, a task unique to sign language acquisition (Harris and Mohay, 1997; Holzrichter and Meier, 2000). Another modification in infant-directed sign involves facial expression. In adult sign language, facial expression has two functions, the affective function, which is universal to humans, and the linguistic function, which is unique to sign languages. In infant-directed sign, adults use only affective facial expression. When children have acquired signs for some facial linguistic markers, around 24 months of age, adults can begin to add more linguistic facial expressions to their infant-directed sign (Reilly *et al.*, 1991; Reilly, 1996).

Infants who experience sign language babble with their hands. Manual babble occurs around the same age as vocal babble, from 6 to 12 months. Manual babble consists of a reduced set of phonological parameters found in the sign language input and follows the syllabic organization of sign languages, especially with respect to rhythmic timing. The handshapes most commonly observed in manual babbling are: [5] (relaxed hand), [A] (fist), [0] (including baby O), and [G] (index point). These handshapes are used with more repetitious movements than they are in the adult model, and movements such as opening and closing the handshape, raising and lowering the hands or arms, and movement toward the body are common. The location (or place) parameter of manual babbling seems to be idiosyncratic; for example, some infants babble in neutral space in front of the body, while others babble mostly on the head or face (Petitto and Marentette, 1991).

The transition from manual babbling to first words occurs around 10 months of age (with large individual variation). Manual babble and communicative pointing decline just before the appearance of the first sign (Petitto, 1987). First signs have been reported from as early as 8 months to as late as 16 months. The first 10 signs are produced around 12 months of age, and the first 50 signs emerge at 24 months and older (Anderson and Reilly, 2002). Children inevitably make signing errors; the phonological parameters used most frequently in manual babble tend to be the most common substitution errors in early sign (see Figure 1). The sign parameters

Table 1 Summary of acquisition of grammatical structures in sign language

Structures	*Age*[a]		*Sign languages*[b]
	Of first appearance	*First mastered*	
Babbling	0;7–0;10	—	ASL, JSL, LSQ
First words	—	0;8–0;12	ASL, JSL, LIS, LSQ
Word combinations			
Two words	1;2–1;6	—	ASL, JSL
Basic word order	2;4–2;6	—	ASL, SLN
Pronouns			
First person	1;8	2;2	ASL
Second person	1;10–2;0	2;2	ASL
Third person	2;0	3;6	ASL
Possessives	2;0	2;4–2;9	ASL
Negation			
Negative signs	1;6	—	ASL
Negative-incorporated verbs	1;6	—	ASL
Negative sign with headshake	1;8	4;0	ASL
Negative-incorporated verb with headshake	2;0	4;0	ASL
Negative predicate with headshake	1;8–2;2	4;0	ASL
Questions			
Yes/no facial grammar	1;0	—	ASL
Question signs	1;6–2;4	—	ASL
Non-manual markers over question signs	3;6	6;0	ASL
Facial adverbials	1;10–2;0	5;0	ASL
Topics	2;9	3;0	ASL
Conditionals			
Conditional signs	3;0	4;0	ASL
Non-manual markers over signs	5;0	7;0–8;0	ASL
Verb agreement			
Agreement verbs without inflection	2;6	—	ASL
Agreement verbs with inflection	3;0	6;0	ASL
AB verbs	6;0	11;0–12;0	ASL, BSL
Perspective shift			
Shift roles with eye gaze	3;0	—	ASL, BSL
Direct quote	3;6	6;0–8;0	ASL, BSL
Non-manual markers	3;6	13;0	ASL, BSL
Classifiers			
Figure (handshapes)	3;0	8;0–9;0	ASL, BSL, SLN
Use of space	3;0	9;0–10;0	ASL, BSL, SLN
Ground	4;0	11;0–12;0	ASL, BSL, SLN

most frequently misarticulated are handshape, followed by movement, with location being the most accurate (Marentette and Mayberry, 2002). Development of motor control is evident in early signs, with movements made by proximal joints, such as the shoulders and elbows, being substituted for movements made by distal joints, such as wrists and fingers (Meier *et al.*, 1998).

Less than a third of children's first signs are composed of vocabulary with iconic qualities. Instead, children's first signs are semantically similar to those of children learning spoken languages. Words closely related to the child's experience appear first, such as words for people, animals, and food. The acquisition of more abstract words is related to the size of the lexicon. Question words, cognitive verbs, and negation all appear after 100 words have been learned, around 18 to 24 months of age (Anderson and Reilly, 2002). Pointing is present in infants' communicative repertoires starting at 10 months of age, but does not lead smoothly into the use of sign pronouns, which are produced using the same form. Until 20 months of age, children use nominals instead of pronouns/possessives to refer to people, and begin using pronouns with errors just before 2 years. The first-person pronoun is acquired first, followed by second person; pointing to a third person who is present precedes the use of abstract locations in space to refer to people

Figure 1 A child's sign error: the child signs 'APPLE' by using the handshape [I] instead of [Ih] and the movement [contact] instead of [twist], in comparison to the mother's correct target sign. Illustration by Michael Shang. Reprinted with permission from Marentette P F & Mayberry R I (2000). 'Principles for an emerging phonological system: a case study of early ASL acquisition.' In Chamberlain C, Morford J & Mayberry R (eds.) *Language acquisition by eye*. Mahway, NJ: Lawrence Erlbaum Assoc. 71–90.

and objects not present, which is acquired after 3½ years (Hoffmeister, 1987; Petitto, 1987).

In the transition from single words to the two-word stage, children begin by combining a gesture, usually a point, with a single word (as is the case for babies acquiring spoken language). This development, around 12 months of age, is called the semantic one-sign stage because the gesture and sign both refer to the same meaning. The semantic two-sign stage follows, at around 16 months, with the point and the sign referring to two distinct meanings. For example, the child may point at an object and sign a verb such as 'EAT', or make a request, such as 'MORE' (Capirci *et al*., 2002; Torigoe and Takei, 2001). Children combine lexical signs once they have a vocabulary of 100 signs, from 18 to 24 months of age. These combinations generally consist of uninflected nouns and verbs such as 'MOMMY EAT' or 'WANT DRINK' or may include quantifiers such as 'MORE CRACKER' (Anderson and Reilly, 2002). After the two-word stage, children begin to acquire the more complex elements of sign languages, such as morphology, that depend on non-manual markers and the linguistic use of space with signs. In general, non-manual markers, or linguistic facial expressions, are neither comprehended nor produced by children until they have acquired the corresponding manual signs. Children begin to use non-manual markers around the age of 2 years, but cannot produce them comparable to the adult model until after 12 years of age. Although children communicate negation using a non-linguistic headshake by 12 months, their first negative signs at 18 months are produced without the obligatory linguistic headshake. They integrate the headshake (with errors in timing and scope) a few months later and use both sign and non-manual negation correctly between 26 and 28 months of age. Similar to the acquisition of negation, facial adverbials, such as 'puff' (puffing the cheeks out, meaning 'very big/fat'), are not acquired until children can express these meanings in signs. Dozens of facial adverbials are acquired much like lexical items are acquired, from the age of 22 months to 4 years and older (Anderson and Reilly, 1997, 1998).

The acquisition of yes/no questions occurs early because there are no signs to be mastered first. Babies use the necessary non-manual marker, generally raised eyebrows, over a single sign as early as 12 to 16 months of age. Questions requesting information require the acquisition of both signs and non-manual markers (such as lowered eyebrows and eye squint). Question signs appear first at 18 months and gradually increase in variety and use until 3 years of age, but non-manual markers are not added consistently or appropriately until 3½ years of age (Anderson and Reilly, 2002). The adult model has a variety of acceptable word orders in questions, and children start using these orders, also adding a redundant question word in sentence-final position, after the age of 4½ years (Lillo-Martin, 2000). Although topicalization uses non-manual markers that are similar to those used in yes/no questions, non-manual markers are not used for topics until the age of 3 years. However, there is some evidence that children can express topicalization using a prosodic break by the age of 2 years (Pichler, 2002).

The development of conditional sentences further demonstrates the dichotomy between the acquisition of the signed and non-manual markers of many syntactic structures. Non-manual conditional markers

are obligatory but conditional signs are not in ASL. From ages 3 to 4 years, children can comprehend the conditional structure in signs, but not in non-manual markers, and they can express some conditionals in signs without the obligatory non-manual markers. By the age of 5 years, children can comprehend non-manual markers but are inconsistent in their production of these structures. The timing and scope of non-manual markers with signing are not fully mastered until the age of 8 years (Reilly *et al.*, 1990).

In many sign languages, verb agreement is marked with the linguistic use of space. Acquiring spatial morphology is a gradual process in which children actively attempt to identify morphological components; this is apparent in the errors they make, which are productive as opposed to being iconic. In general, around the age of 3 years, children can comprehend the use of locations in space for verb agreement before they can produce it. At the same time, they are able to inflect verbs using people, places, and objects that are present. The period from age 4 to 5 years is the time in which they comprehend verb agreement but produce it with errors, such as overgeneralizations to verbs that cannot take agreement. Correct production of basic verb agreement is acquired by the age of 6 years (Meier, 1987, 2002). Shifting directional verb agreement, involving what are known as AB verbs, is a kind of verb agreement that takes children longer to grasp. In this case, three thematic roles are mapped onto two-argument verbs. In English, this could be expressed as *John hit Peter on the head*. In many sign languages, this is expressed using two parts, A and B. In A, the verb agrees with person X and person Y. In B, the verb agrees with person Y and the part of the body being affected (in this case the head). Children can comprehend AB verbs (ages 3 to 5 years) long before they can produce them. Usually, children will attempt to produce these verbs using only the B part, omitting the subject information. Between the ages of 6 and 8 years, they will sometimes produce only one part, and usually omit the obligatory perspective shift. Production of AB verbs is mostly correct by 9 years of age, although it takes a few more years for the non-manual markers to become fully adultlike (Morgan *et al.*, 2002).

The acquisition of sign language structures referred to as classifier constructions is protracted, because full mastery requires the adept combination of several linguistic skills. Children must be able to use an array of signs alongside classifier handshapes, must coordinate both hands so that they can work together to track figure and ground, and must know when to introduce a referent with an identifying sign versus a classifier. Before they start using classifiers, children first use the bare form of the verb to describe an action. Also, children focus entirely on the action involved, do not focus on the figure, and generally omit the ground. By 5 or 6 years of age, children can select appropriate semantic classifier handshapes without specifying all of the relevant dimensions, and they start to distinguish the beginning and end of the action. Children are able to show facial affect with classifier constructions and change the orientation of the non-dominant hand to represent the ground by the age of 8 years. By age 9½ years, their classifier constructions are mostly correct. Nonetheless, children do not properly specify the ground in classifier constructions until 11 or 12 years of age. In mastering classifier constructions, children tend to focus first on the action and then begin to add information about the figure; finally, they are able to specify the ground (Engberg-Pedersen, 2003; Slobin *et al.*, 2003).

Reported action in many sign languages requires the mastery of perspective shift, which is important to narration. Children need to understand the concept of shifting viewpoint and must be able to produce several different non-manual markers. From ages 3 to 4 years, the only evidence that children are changing perspective is in their eye gaze shift; some children may use a character facial expression incorrectly. Around 5 years of age, children transition to expressing perspective shift linguistically by first labeling a character and then signing 'SAY' to introduce a direct quote. Most children of this age also correctly take on the facial expression of the character, although they tend to stay fixed in one perspective (whereas adults are capable of changing perspectives rapidly and often). By ages 6 and 7 years, children have mastered the signed and most of the non-manual markers for a direct quote, but they continue to have difficulty with reported action; i.e., whereby the narrator reports a character's actions and takes on the facial expression of that character while remaining in the role of narrator. At this point, children tend to tell narrations solely from a narrator's viewpoint using primarily linguistic, as opposed to paralinguistic, means. They gradually integrate paralinguistic devices with perspective shift after 8 years of age. Finally, as in most structures that use complex non-manual markers, the non-manual markers for character perspective and reported action do not become adultlike in narration and discourse until age 12 years and older (Morgan *et al.*, 2001; Reilly, 2001).

Cross-linguistic research shows that linguistic structure remains abstract when it is understood through the eyes and expressed with the hands, arms, and face. Children who are acquiring sign languages face the same challenges that children acquiring spoken languages face. They must discover the

underlying units and rules of the words, sentences, and discourse patterns of the language around them. Like children acquiring spoken languages, children acquiring sign languages are highly analytic and acquire grammatical structure one piece at a time through communicative interactions with the people who care for them.

Sign Language: Communities and Cultures

P Ladd, University of Bristol, Bristol, UK

© 2006 Elsevier Ltd. All rights reserved.

In Western industrialized societies, sign language-using Deaf people form a small percentage of the population (around 1 in 1000). Their numbers are augmented by the non-Deaf children who have sign language-using parents, and in recent times by growing numbers of non-Deaf people who have taken formal classes to learn the sign languages of those nations. In the UK, the latter number over 100 000 (Woll, 2001), but figures for other countries are not known, although it is estimated that in the United States these numbers exceed 1 million. However, the center of those sign language communities revolves around those (mostly Deaf people) who participate in the daily lives of those communities and have a stake in the ongoing future and their quality of life. They are characterized by intermarriage, and it is estimated that 90% of Deaf people who marry choose Deaf partners.

A History of the Western Concept of Deaf Community

It is probable that Deaf people who communicate by gesture or sign have existed as part of humanity from its inception; in the West, the first written evidence of their existence can be found at the dawn of Western literacy itself, with the rise of the Mediterranean societies in the 5th century B.C. From that time onward, Greek philosophers such as Herodotus, Socrates, Aristotle, and Plato, and their equivalents in Jewish and Roman society, found the existence of signing Deaf people illuminating when considering wider issues concerning human thought and behavior, and philosophized about the nature of Deaf people's existence and their place in society, eventually establishing laws relating to them.

In these discourses, many of which suggest the existence of Deaf communities even then, two contrasting positions can be identified between those who present a positive or negative view of Deaf peoples and their potential.

Deaf 'Emergence' in the Middle Ages

Little is known of Deaf communities until the 15th century, when, for a number of complex reasons, including the impact of the Renaissance with its revival of Greek philosophy, there was a considerable increase in both discourses. One strand concerns the education of Deaf people, while others indicate an emerging recorded respect for Deaf people by lay society; achievements by Deaf individuals and groups in artistic and business domains (Miles, 1988; Mirzoeff, 1995); the existence of Deaf networks (Bulwer, 1648); and communities that incorporated sign language into their everyday lives (Groce, 1985). A further theme considers the importance and status of visual gesture in some societies during these periods (Mirzoeff, 1995); these may have underpinned a more positive view of Deaf people.

In Western industrialized societies, sign language-using Deaf people form a small percentage of the population (around 1 in 1000). Their numbers are augmented by the non-Deaf children who have sign language-using parents, and in recent times by growing numbers of non-Deaf people who have taken formal classes to learn the sign languages of those nations. In the UK, the latter number over 100 000 (Woll, 2001), but figures for other countries are not known, although it is estimated that in the United States these numbers exceed 1 million. However, the center of those sign language communities revolves around those (mostly Deaf people) who participate in the daily lives of those communities and have a stake in the ongoing future and their quality of life. They are characterized by intermarriage, and it is estimated that 90% of Deaf people who marry choose Deaf partners.

A History of the Western Concept of Deaf Community

It is probable that Deaf people who communicate by gesture or sign have existed as part of humanity from its inception; in the West, the first written evidence of their existence can be found at the dawn of Western literacy itself, with the rise of the Mediterranean societies in the 5th century B.C. From that time onward, Greek philosophers such as Herodotus, Socrates, Aristotle, and Plato, and their equivalents in Jewish and Roman society, found the existence of signing Deaf people illuminating when considering wider issues concerning human thought and behavior, and philosophized about the nature of Deaf people's existence and their place in society, eventually establishing laws relating to them.

In these discourses, many of which suggest the existence of Deaf communities even then, two contrasting positions can be identified between those who present a positive or negative view of Deaf peoples and their potential.

Deaf 'Emergence' in the Middle Ages

Little is known of Deaf communities until the 15th century, when, for a number of complex reasons, including the impact of the Renaissance with its revival of Greek philosophy, there was a considerable increase in both discourses. One strand concerns the education of Deaf people, while others indicate an emerging recorded respect for Deaf people by lay society; achievements by Deaf individuals and groups in artistic and business domains (Miles, 1988; Mirzoeff, 1995); the existence of Deaf networks (Bulwer, 1648); and communities that incorporated sign language into their everyday lives (Groce, 1985). A further theme considers the importance and status of visual gesture in some societies during these periods (Mirzoeff, 1995); these may have underpinned a more positive view of Deaf people.

The Development of Sign Language Education

As Deaf educational establishments began to bring together large numbers of Deaf children and adults, sign languages began to flourish (cf. de L'Epée, 1984). Although it can be argued that Deaf people can maintain satisfactory lifestyles while existing outside education systems (cf. Desloges in Lane and Philip, 1984), there is no doubt that the concentration of Deaf children and adults within a residential school system is the single most important factor in maintaining a sizable and healthy Deaf community. Deaf education therefore was, and continues to be, the battleground on which the community's future existence and quality of life is contested.

By the early 19th century, the numbers of Deaf graduates from these schools created a demand for Deaf meeting places; large numbers of clubs and religious societies were consequently established across Europe and the United States, many again founded by Deaf people themselves (Lysons, 1963), and thus the first modern Deaf communities were created. For the first time, Deaf school graduates attained professional positions, and Deaf magazines and newspapers were developed to facilitate regional and national communication. These developments were enhanced by the establishment in the United States in 1867 of Gallaudet College, the world's first (and only) Deaf university.

Documents from the era show high levels of Deaf self-confidence (Mottez, 1993), including beliefs about the importance of possessing (God-given) languages with the potential to be globally understood. This embodiment of world citizenship was seen as setting an example for spoken language users, to whom they wished to extend this globalizing opportunity.

The national Deaf communities were perceived as a single global community with national branches in each country of the world. Although this represents an elevated epistemology within Deaf discourses, the persistence of such thought right through to the present day indicates that Deaf communities cannot be truly understood if this dimension is not grasped. In the process of developing such discourses, attempts were also made toward formalizing the concept of individual enfranchised or independent 'Deaf-Mute Nations', for example in France (Mottez, 1993) and the United States (Van Cleve and Crouch, 1989).

Although limited educational opportunities meant that only a percentage of Deaf children in each country were able to come together in the schools and clubs, sufficient numbers began to travel internationally and establish formal links with other national Deaf communities. This led to the founding of international congresses, initially focused on the agendas of Deaf professionals, but which by the early 20th century multiplied to encompass sports and other specialized associations.

Sign Languages and Linguistic Colonization

However essential to sign language community development, the expansion of Deaf schools and clubs also created something of a Trojan horse. Deaf education itself was often presented as presupposing non-Deaf masters of Deaf subjects (e.g., Sicard, 1984), and an ideology of the miracle of Deaf education, that is, the rescuing of Deaf people from subhuman status, was disseminated to lay people. Deaf leaders, seeking money to establish more schools, had little choice but to go along with this; a similar pattern occurred in the development of Deaf clubs. This pattern of control having been established, Deaf communities were vulnerable when the methodologies of the education system changed.

As the 19th century continued, the growth of industrialization saw the development of self-justifying tropes of *science* and *progress*, which began to construct Deaf people within the regressive trope of *Nature*, that is, as something that could be changed for the better. Developments in these domains were reinforced by the concerns of healthy parents of Deaf children who controlled the funding of the charitable and private school. Many wished their children to remain within their own social groups, and not to join communities of the Deaf multitudes.

All these themes coalesced in the doctrine of Oralism, which sought to remove sign languages and Deaf teachers from the schools, to replace them by advocating the sole use of spoken communication, and thus to forbid Deaf children from signing with each other. These culminated in the famous Milan Conference of 1880. The power embodied in the ruling bodies and their control of the media resulted in rapid dissemination of this message; a useful example is the proclamation by the *London Times* that "Deafness is abolished," only days after the conference. Emerging at a time when the centralization processes of the nation-state were advancing rapidly, the Oralist philosophy was able to swiftly attain hegemonic status.

However, in the first phase of Oralism, when Deaf communities were still strong and their leaders still qualified and experienced professionals, the communities and their allies were able to respond by founding national organizations to combat Oralism; the National Association of the Deaf (NAD) was established in the United States in 1880, and the British

Deaf and Dumb Association (BDDA) in the United Kingdom in 1890, both of which still exist today. International congresses were held, culminating in Paris in 1900, where Deaf teachers and headmasters attempted to join the conference intended to ratify Milan. This battle was lost, and although the communities never gave up demanding change, their prime focus turned inward, toward preserving their language and their community and developing their own social structures. Thus Oralism was to remain essentially unchallenged for the next 70 years.

Once Deaf teachers were removed, Oralism was able to enshrine itself as a system of linguistic colonization (Lane, 1993; Ladd, 2003). National governments sought to remove sign languages from the lives of Deaf children with the intent that they be assimilated into majority societies, using only those languages. In effect, this implied the removal of sign language communities from existence.

An outgrowth of these discourses, a Social Darwinist eugenics discourse also resulted in attempts to close Deaf clubs, to prevent Deaf marriages, and laws to sterilize or castrate Deaf people were placed on the statute book of 30 U.S. states (Mirzoeff, 1995) by the 1920s, in Sweden in the 1930s, reaching its apogee across Nazi-occupied territories. These policies too were designed in the hope of removing those languages and communities from existence altogether (cf. Bell, 1984).

During the dominance of this discourse, Deaf people's positive image with the lay public was diminished; earlier perceptions of an organic community with philosophical significance were supplanted by the medical-model perception of a collection of isolated and handicapped individuals who constituted a medical and social problem. Oralist discourses suggested that lay attitudes toward Deaf people were irrevocably negative, so that they were justified in taking upon themselves the mantle of caring for such social outcasts. Moreover, given these supposedly negative attitudes, there was no possibility that lay people would be willing to learn sign language; thus communication with them was conceived of as based solely on the spoken word.

Deaf Communities' Resurgence

In the mid 1970s, growing awareness of the failure of Oralism, combined with the decolonization processes engendered by the liberal 1960s, enabled the beginnings of a Deaf resurgence. A number of factors contributed to this process: the development of welfare states, which weakened the hold of the charitable sector over Deaf community life; Deaf activist movements, such as the National Union of the Deaf in the UK, and the revolt to achieve a Deaf President at Gallaudet University in the United States; the Total Communication (and later bilingual/bicultural) movement, which sought to restore sign languages to Deaf education; Deaf visibility in the media, especially in the creation of Deaf TV programming itself; linguistic recognition of sign languages, public prominence of sign language interpreters; and the rediscovery of Deaf history, culture, and arts. These have culminated in the very recent development of Deaf Studies as an academic discipline.

Although it is too early to speak of a Renaissance as opposed to a resurgence, the larger numbers of Deaf children educated in sign languages who have now reached maturity have taken advantage of the developments above to create new dimensions of Deaf cultural and artistic activities, perhaps most notably observed at the two international Deaf Way congresses of 1989 and 2002, the latter drawing 15 000 participants from across the world.

Once Oralism's grip was weakened, sign languages rapidly emerged from their century-long comparative invisibility, so that large numbers of non-Deaf persons have learned the languages, effectively extending the concept of sign language communities by becoming fringe members of Deaf communities themselves.

Among the numerous ramifications of these developments has been the recent moves toward official governmental recognition of sign languages, and consequently their communities and cultures. Several countries, including the United Kingdom and most Scandinavian countries, have pronounced such recognition, although the implications of recognition have not yet been translated into consistent decolonizing praxis. Recognition by the European Union, although not legally binding on member states, has proved the most significant in as much as it has brought sign language communities into direct contact with European minority language organizations.

Despite these positive developments, both Oralism and more liberal beliefs in linguistic assimilation have continued and can even be said to have intensified with the enforced mainstreaming of Deaf children (as many as 95% in the case of the United Kingdom) and the closure of hundreds of Deaf schools.

Cross-Categorization of Deaf Communities

In this ensuing battle, the unique status of Deaf communities is itself a problem. To define them simply as disabled is to overlook the linguistic foundation of their collective life. To define them as a linguistic group is to overlook the very real sensory characteristics of their existence, both positive (a unique

visual-gestural-tactile perception of life around which sign languages have been constructed), and negative (communication barriers are not simply linguistic, but auditory, too).

Conventional definitions of cultures also appear to thwart easy recognition of Deaf culture. The characteristic of ethnicity is rendered problematic because only 5–6% of Deaf children at most are born to two Deaf parents (Kyle and Woll, 1985), posing questions in relation to conventional ideas of cultural transmission. Traditional theories also emphasize that cultural development is involuntary; since individuals are socialized into their community from birth, questions are raised concerning the cultural validity of choosing to be Deaf.

Additionally, Deaf communities do not have their own land, nor live (or even choose to live), as geographically intimate communities. There are also very few material productions that are Deaf, compared to those of many other cultures. Finally, doubt has been expressed as to whether Deaf cultures have ontological systems, which most other cultures possess. Although these arguments can be refuted (cf Ladd, 2003), they can only gain prominence if the world in general develops a more profound understanding of the concept of culture itself.

Deaf Cultures

The term 'culture' in relation to descriptions of Deaf collective life occurs first in Stokoe *et al.* (1965) where an appendix describes the social and cultural characteristics of Deaf people. By 1975, Padden and Markowitz (1975) were defining community as "a group of persons who share a common culture," and applying this to Deaf communities.

Baker and Cokely (1980) establish a contrast between definitions of Deaf people from clinical-pathological and cultural perspectives. However, they do not use the latter term again, listing instead four factors – linguistic, political, audiological, and social – with the last doing duty for what might now be thought of as cultural. Their approach is perhaps the most influential of perspectives; Kyle and Woll summarize that "[this seems] to be the most consistent of the theoretical views of the community" (Kyle and Woll, 1985: 8).

It is not until Padden (1980) that a specific definition is attempted for the culture of American Deaf people. Having taken culture to mean "A set of learned behaviours of a group of people who have their own language, values, rules for behaviour, and traditions" (Padden, 1980: 92), she then states: "Members of the Deaf culture behave as Deaf people do, use the language of Deaf people, and share the beliefs of Deaf people towards themselves and other people who are not Deaf" (Padden, 1980: 93) and concludes that "the most striking characteristics of the culture of Deaf people is their cultural values – these values shape how Deaf people behave and what they believe in" (Padden, 1980: 95).

Like a number of other studies, Higgins' (1980) study, although sociological, describes numerous cultural features such as membership criteria and attitudes of different groups of Deaf people to each other.

During the 1980s, use of the term spread widely, although most described aspects of Deaf culture rather than attempting to measure or comprehend its totality. Bienvenu and Colonomos (1986) among others, begin to use the term as an all-encompassing framework and give taxonomic descriptions, some of which are rather unsystematically constructed.

There has been some controversy within the American Deaf community around the spread of the sign DEAF CULTURE, some arguing that the original Deaf terms such as DEAF-HIS and DEAF-WAY are good enough. Nevertheless, Bahan (1994: 245) discusses the term DEAF CULTURE, how it has begun to be accepted and has started to develop an extra level of meaning: "There are Deaf people who go out and say to others, 'YOU NOT DEAF CULTURE'." Asserting that there was never a time when any Deaf person would go up to another and say 'YOU NOT DEAF WORLD', he concludes that: "What the [first comment above] is making them do is to assess different things that they have internalized while growing up. It becomes an avenue for checking into the values and patterns that one has internalized in the hearing world. It is not that those hearing values are bad, but rather, it is a reminder that this is now our world you are in" (Bahan, 1994: 245). Bahan's conclusions lead one to ask whether past Deaf communities did not attempt to exclude or criticize other Deaf people, or whether it is simply the recent emergence of Deaf pride that has led to such distinctions. They also suggest that one can be in a Deaf community (Deaf World), but not have, or always manifest Deaf Culture.

Academic Perspectives on Deaf Culture

From the 1980s onward, writers have examined Deaf culture within frameworks they have devised or adopted, such as membership perspectives. Padden and Humphries (1988) proposed a refinement of Woodward's definition: "We use the lowercase *deaf* when referring to the audiological condition of not hearing, and the uppercase *Deaf* when referring to a particular group of deaf people who share a language . . . and a culture" (Padden and Humphries, 1988: 2).

The same authors also provided a symbolist perspective in the first book-length text on Deaf culture, developing an anthropological (Geertzian) perspective of what it means to operate from within one's Deaf identity, with themes such as learning to be Deaf, images of being, the meaning of sound, and historically created lives.

Carmel (1987) and Rutherford (1993), in their focus on Deaf identity issues, also work from anthropological perspectives to bring to the surface deeper examples as manifested in symbolic relationships, focusing particularly on Deaf folklore.

Other accounts operate from linguistic perspectives, seeing sign language as the one clearly unique cultural characteristic of the Deaf community. As Kannapell (1982) eloquently puts it, "ASL is the creation which grows out of the Deaf community. It is our language in every sense of the word. We create it, we keep it alive, and it keeps us and our traditions alive."

Johnson and Erting (1989) present an ethnicity perspective. This is concerned that the treatments reviewed above are taxonomic: "basically labelling theories which place people in groups on the basis of interpretations made by those who are doing the labelling" (Johnson and Erting, 1989: 44) as they go on to say: "Such labels can correspond to salient behaviours and values of a cultural group but they are unlikely to provide substantial insight into the processes that account for the emergence and maintenance of those values and behaviours as identifying features ... For this reason we align ourselves with anthropologists who study phenomena similar to the Deaf sociocultural experience under the title of ethnicity" (Johnson and Erting, 1989: 44).

Other anthropological perspectives draw on linguistic, membership, ethnicity, and structuralist perspectives, but are notable chiefly both for the amount of anthropological data given, and for an emphasis on examining diversity within the Deaf community.

All these perspectives being very recently developed, there have been few attempts to cross-reference each, apart from Turner (1994a, 1994b), and thus to begin to find a workable consensus. Likewise, since most have not produced a sustained subaltern-oriented ethnography, there is little hard data for others to reinterpret.

Thus most of these perspectives remain taxonomic, focusing on differences between Deaf and hearing cultures rather than exploring Deaf culture in and of itself. Consequently they fall victim to what Wright has summarized in another context as "the old idea of culture":

- bounded, small-scale entity
- defined characteristics (checklist)
- unchanging, in balanced equilibrium or self-reproducing
- underlying system of shared meanings: 'authentic culture'
- identical, homogenous individuals (Wright, 1998: 8).

Recent Developments

The work of Mindess (2000) was something of a breakthrough. Although not addressing these weaknesses she provides an in-depth analysis of Deaf cultural features based on cultural categories developed by the new discipline of inter-cultural communication. Ladd (2003) addresses these weaknesses by identifying cultural patterns across generations in the United Kingdom, and showing how these are affected by class distinctions within the community. By developing a model of Deaf cultures as minority cultures, he also illustrates how majority society and colonialist cultural values are absorbed into Deaf cultures themselves, often with negative effects.

Other Deaf Communities

Although the cultural patterns above are characteristic of Western Deaf communities, similar patterns can be found in so-called developed countries such as Japan, Australia, and New Zealand.

There are at least four other models of Deaf communities that can be identified. The first, rudimentary or ur-communities, describe those communities in the West prior to Deaf education; these are still found in many Third World countries today. They are characterized by very small localized gatherings of Deaf people, the majority being isolated within the general population, and by a gradual move toward larger communities in urban areas, especially the capital cities.

The second represents communities where some Deaf schools have been set up but where large numbers of Deaf children do not attend schools and/or there is a less developed local, regional, or national Deaf infrastructure. This description of such a developmental stage roughly parallels that reached in the mid-19th century in the West, and can be applied to many Latin American and Asian Deaf communities, as well as several African countries. Although Oralism was exported to these countries (as in almost every part of the world), the last decade has also brought the beginnings of a Deaf resurgence, with sign languages used in many Deaf schools, and through the work of the World Federation of the Deaf (WFD) and others, national organizations and official WFD regions have been formed. Indeed, in some of these countries, such as Columbia, Uganda,

and South Africa, the indigenous sign languages have been granted official recognition.

The third and fourth, characterized by Woll and Ladd (2003) as integrated communities and single communities, indicate that the socioeconomic status and educational achievements of Deaf people is largely equivalent to that of hearing people, that there is a higher rate of endogamous marriage, and that the hearing communities have awareness of the Deaf community, including a degree of knowledge of those sign languages. It cannot as yet be confirmed that Deaf communities in each of these examples engage in their own separate gatherings, but if they do, they can be characterized as Deaf subcommunities.

Erting *et al.* (1994) include several accounts of communities in Nepal, Pakistan, Burundi, and Ghana. There have also been a number of studies of more isolated signing communities, including Grand Cayman Island; Providence Island, off the coast of Colombia; several villages in Surinam; the Urubu of Amazonia; Martha's Vineyard (from the 17th to 19th centuries); the Enga of New Guinea; the Yucatan; Bali; and a Bedouin tribe.

Schmaling (2000) provides a thorough and grounded description of a well-established Deaf community of this type, the Deaf community of Northern Nigeria, which is briefly described below to give an idea of what such Deaf communities might be like.

Although there are no written historical records of Deaf Hausa people, oral tradition reports that Deaf people have always had meeting points in towns and villages where they met to share information and experiences. Members of the Deaf community share a common language, Hausa Sign Language. The Deaf community has its own leader, the Sarkin Bebaye (Chief of the Deaf) whose office is regarded as that of representative of the Deaf, paralleling the system of chiefs which is one of the basic organizational principles of Hausa society.

Deaf people are well integrated into hearing Hausa society. As a result, interaction and communication between Deaf and hearing people is high. Many hearing people are able to converse with the Deaf freely and effectively through signing, at least on a basic level. Hearing people do not feel ashamed of talking with the hands; they generally try to use their hands as much as possible when communicating with Deaf people and accept that signs or sign language are the medium of communication for Deaf people. Schmaling discusses a number of features that may account for the high level of integration of Deaf people in Hausa society, including a high incidence of Deaf (and deafened) people, and a life primarily conducted in a hearing extended family. Another, of interest given what follows below, is that Islam, the majority religion, promotes the belief that everything is from God, so society is generally accepting of deafness. In addition, as prayers are not spoken aloud, Deaf people can fully participate in religious activities.

Schmaling does report that there is a danger that this state of integration may weaken, as individualization progresses with a loss of traditional societal values. In the case of Desa Kolok in Bali, this process may be exacerbated by the establishment of a residential school away from the village. A similar development resulted in the Martha's Vineyard community slowly moving away from the island, joining with the Deaf community formed around the mainland residential school (Groce, 1985).

A rare example of a Deaf community that appears to have a higher status than many of the hearing people in that society was identified by Miles (2000). The (Islamic) Ottoman court from 1500 to 1700 and possibly later was ruled by a succession of sultans who appear to have granted sign language higher status than spoken language for use in their presence. This led to them actively recruiting Deaf people, as many as 200 at one time, to teach hearing people the language. The Deaf seemed to have formed an identifiable community within the Court, marrying among themselves and distinguishable also by their own livery. They also seemed to be granted special status with the sultans themselves, being chosen as close companions or for specific military tasks.

Western Deaf Subcommunities

Increasing social mobility and professional status, together with the growth in numbers of non-Deaf signers, has had the effect of creating small subcommunities of Deaf and hearing signers around towns or cities containing Deaf schools and universities. Bienvenu and Colonomos (1989) refer to these types of development as constituting a *third culture*.

In recent years, researchers have also begun to identify Deaf subcommunities oriented around ethnicity. These include, in the United Kingdom, Asian (Taylor and Meherali, 1991) and Afro-Caribbean Deaf peoples (James and Woll, 2002). Although these overlap to some degree with majority Deaf communities in social activities, the relationship between the two is problematic. In the United States and South Africa, where Deaf communities were segregated through apartheid policies, the traditional construction asserted a 'majority' (white) Deaf community and Black Deaf subcommunities. It is now understood that such an attitude is in itself born of racism, and concerted efforts are now being made to reunify the community.

Similar patterns can be identified around religion (Jewish and Roman Catholic Deaf communities) and sexual preference. In some cases, notably the latter two, there is evidence to suggest that distinctive sign dialects exist.

It also appears to be the case that in some countries where mainstreaming policies are especially advanced, Deaf youth are now beginning to form their own subcommunities and thus have limited contact with the traditional communities. Indeed, although many appear to move toward such communities in order to escape from isolation and begin the process of learning sign language upon arrival, there is evidence that due to the concept of critical mass, significant numbers are either learning the language superficially or barely at all.

These patterns also appear to be exacerbated by the spread of cochlear implantation among the young. Such developments, together with the rise of genetic engineering and the threat of removal of the Deaf genes, pose an immense challenge for the future of Western Deaf sign languages and thereby their communities. Their long-term future is once again placed in doubt, although it is clear that many of these will resist their potential eradication. Perhaps their most powerful tool remains with recognition of their linguistic status, and their support from other threatened minority languages, since this discourse stresses that it is a breach of the United Nations Charters to attempt to exterminate any of the world's languages and cultures.

Sign Language: Discourse and Pragmatics

R B Wilbur, Purdue University, West Lafayette, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

Culture and the Pragmatics of Discourse

In every culture, conversations have structures that reflect their values, for example, whether the information provided is truthful, or satisfies the questioner, or is polite. As an example, Weiser (1975) notes that an answer can be acceptable in discourse if the answer addresses the questioner's purpose for asking the question. She illustrates this with (1):

(1) Q: How old are you?
A: Don't worry, they'll let me in.

The questioner thinks something like: We are going to a bar; there is a minimum age of 21 to get in; I wonder if my date is old enough. The questioner asks for specific information. The date responds with reassurance that his underlying concern will not be a problem. The date's age remains a mystery. Such a conversation is considered polite in a culture that places high value on not invading a person's privacy by requesting personal information, such as age.

Conversational style and structure differ significantly between Deaf and hearing communities. Because signers can see, and be seen by, anyone who is present, it is especially difficult to maintain privacy. Furthermore, as Hall (1989) observes, the Deaf community functions as a surrogate family – everyone knows everyone. The politeness conventions that dominate Deaf community interactions help promote unity among the Deaf. Since maintaining privacy is problematic, conversations among Deaf people lean toward the opposite – being more direct, which may feel intrusive to people unfamiliar with this cultural priority. Attempts at evasive answers may lead to joking, teasing, and not-so-subtle prodding.

Minority Language Status and Signing Style in Discourse

As with spoken languages, there are sign register differences, such as formal/informal articulation, larger signing and signing space when 'shouting' across the room, and so on. Signing style is also heavily affected by its minority language status, especially when hearing people are present. If the hearing people are supposed to be conversational participants but do not know sign, signers may switch to voice and speak the dominant spoken language, or they may resort to writing with paper and pen. Others may continue to sign, but in an altered form that involves speaking while putting the signs into the word order of the dominant language (known as 'signed English,' 'signed Croatian,' etc.). Such simultaneous speaking and signing is a hybrid communication technique that distorts both speech and signing, and is not itself a natural language (Wilbur and Petersen, 1998). If the hearing people do know some signing, Deaf signers may continue in their own sign language, but with a slowed signing rate, and perhaps with altered choice of signs. There is a signing style (rate of signing, lexical choice, use of facial expressions) reserved for use among members of the Deaf community.

Sign Language: Discourse and Pragmatics

R B Wilbur, Purdue University, West Lafayette, IN, USA

Culture and the Pragmatics of Discourse

In every culture, conversations have structures that reflect their values, for example, whether the information provided is truthful, or satisfies the questioner, or is polite. As an example, Weiser (1975) notes that an answer can be acceptable in discourse if the answer addresses the questioner's purpose for asking the question. She illustrates this with (1):

(1) Q: How old are you?
A: Don't worry, they'll let me in.

The questioner thinks something like: We are going to a bar; there is a minimum age of 21 to get in; I wonder if my date is old enough. The questioner asks for specific information. The date responds with reassurance that his underlying concern will not be a problem. The date's age remains a mystery. Such a conversation is considered polite in a culture that places high value on not invading a person's privacy by requesting personal information, such as age.

Conversational style and structure differ significantly between Deaf and hearing communities. Because signers can see, and be seen by, anyone who is present, it is especially difficult to maintain privacy. Furthermore, as Hall (1989) observes, the Deaf community functions as a surrogate family – everyone knows everyone. The politeness conventions that dominate Deaf community interactions help promote unity among the Deaf. Since maintaining privacy is problematic, conversations among Deaf people lean toward the opposite – being more direct, which may feel intrusive to people unfamiliar with this cultural priority. Attempts at evasive answers may lead to joking, teasing, and not-so-subtle prodding.

Minority Language Status and Signing Style in Discourse

As with spoken languages, there are sign register differences, such as formal/informal articulation, larger signing and signing space when 'shouting' across the room, and so on. Signing style is also heavily affected by its minority language status, especially when hearing people are present. If the hearing people are supposed to be conversational participants but do not know sign, signers may switch to voice and speak the dominant spoken language, or they may resort to writing with paper and pen. Others may continue to sign, but in an altered form that involves speaking while putting the signs into the word order of the dominant language (known as 'signed English,' 'signed Croatian,' etc.). Such simultaneous speaking and signing is a hybrid communication technique that distorts both speech and signing, and is not itself a natural language (Wilbur and Petersen, 1998). If the hearing people do know some signing, Deaf signers may continue in their own sign language, but with a slowed signing rate, and perhaps with altered choice of signs. There is a signing style (rate of signing, lexical choice, use of facial expressions) reserved for use among members of the Deaf community.

Modality Effects on the Pragmatics of Discourse Structure

Conversations in sign language always take place face-to-face, even when facilitated by new technology such as web cameras that allow signers to be seen across great distances. Face-to-face interaction is likely to be infrequent among people who live at distances from each other, and may be limited in duration. This may be the reason for a prominent characteristic of signed conversations, namely, that they start informally, get right to the point, and conclude formally and slowly (Hall, 1989 for ASL). In contrast, American speakers of English begin formally and slowly, conclude informally and quickly, and tend not to be direct about getting to the main point.

Getting Attention

Conversations in SLs require the participants to be paying attention to each other. Ways to obtain attention include waving at or tapping someone, or enlisting a third person to help with this procedure. In larger groups, the lights may be flicked off once or twice to get everyone's attention.

Saying Good-bye

It takes a while to say good-bye to each person in a conversation or large gathering. Saying good-bye ends a face-to-face interaction, leaving communication to be resumed at some uncertain future time. Thus, saying good-bye includes some discussion of when that might be, such as other upcoming events.

Turn Taking

Hand Position Given that all interaction is face-to-face, an orderly system of turn taking is necessary to ensure that participants do not miss part of the communication. Baker (1977) observed regulators that mark turns within conversations, such as hand position. When a signer is listening and not intending to take a turn, the hands are down. When a signer is preparing to sign, perhaps to interrupt or waiting for a turn but wants the current signer to acknowledge that he is waiting, the hands assume half-rest position, generally at waist level. Hands higher than this are in quarter-rest position, a strong indication to the current signer to yield the floor. Of course, a signer can simply begin to sign and hope that the other signer will yield the floor. The floor is yielded by returning hands to full-rest or half-rest position as an indication of wanting the floor back.

Nonmanuals Eye contact plays a significant role in regulating conversational turns. A conversation cannot begin without eye contact between participants, after which the addressee must continue to watch the signer, but the signer is free to look away, for organizing thought or maintaining the floor. As in speech, the signer must check back with the addressee to be certain that the addressee is following the conversation. A signer can ignore an interruption by not establishing eye contact with the person attempting to interrupt (Baker, 1977).

Information Flow and Discourse Structure

Information Flow and Focus

The presentation of information in a discourse is structured according to the sender's belief regarding the receiver's knowledge and attentional state (whether something is in the receiver's mind at the time). Gundel (1999) separates three types of 'focus': psychological 'salience'; semantic 'new information'; and contrastive focus. Psychological focus is what the sender and addressee are attending to. Joint attention ensures that what is the current center of attention is salient to both partners, making it old or given: the 'topic' of conversation. Linguistically, nonfocused information tends to be referred to with pronouns (which refer back to something), definite articles ('the') in languages that have them, and pro-drop in languages that allow it (that is, not expressed at all in the sentence).

In contrast, the term 'focus' is used to refer to new information. By definition, all sentences have new information (Gundel's 'semantic focus'). This is the assertion of the utterance; that part which cannot be deleted. Other terms used for the new information include 'comment' in topic-comment constructions, and 'rheme' in theme-rheme constructions. The term 'focus' will be used here.

Focus Prominence Placement and Marking

Broad Focus Every language has a procedure for determining (a) where the stress prominence falls in a 'neutral' sentence, that is, one that is entirely in focus; and (b) how the prominence will be marked phonetically. When the whole sentence is in focus, stress may be placed on whatever word happens to occur in a particular position, such as final. Or it may be placed on the last lexical item, ignoring functional words. Other strategies include placing it on the last argument of the predicate, or if that argument is a phrasal constituent, on the lexical head of the phrase.

In spoken languages, the marking of linguistic stress itself may include increased duration of the prominent item, higher fundamental frequency (pitch), and increased amplitude. SLs do not have

access to pitch. Research on ASL shows that it uses increased peak velocity of signed movement for stress prominence, and uses increased duration of signs primarily for Phrase Final Lengthening (Wilbur, 1999). ASL also has many other cues to indicate stress, including nonmanuals of head and eyes, and body leans, discussed below.

Narrow Noncontrastive Focus When the whole sentence is not in focus, a variety of distinctions are made. The first is Gundel's 'semantic' focus or what Dik (1989) calls 'completive' focus. This is the part of the sentence that provides the relevant new information; if someone asks 'What flavor do you want?' and the answer is 'I want chocolate,' 'chocolate' is the focused part of the sentence and 'completes' the exchange. A second is focus particles, such as 'even,' 'only,' 'both,' and 'also,' which are traditionally distinguished as lexical focus markers; the items they focus on are called 'focus associates.' In ASL, the sign glossed as SAME functions as 'even,' and ONLY-ONE as 'only.' The focus associates may precede or follow the particle; if it precedes, a brow raise is required on the associate but not on the focus particle. A third is intensive focus, which uses reflexives, e.g., 'Only the defendant *herself* remained completely calm.' In ASL, the sign SELF is used for this.

Narrow Contrastive Focus A more emphatic type is 'contrastive' focus. Gundel argues that contrastive focus is used "because the speaker/writer doesn't think the addressee's attention is focused on a particular entity and for one reason or another would like it to be, because a new topic is being introduced or reintroduced (topic shift), or because one constituent (topic or semantic focus) is being contrasted, explicitly or implicitly, with something else" (Gundel, 1999: 296). By this definition, 'topics' can be 'focused' when they are new or reintroduced.

When contrastive focus selects a correct form from a closed and known set (Dik's 'selecting' focus), ASL uses a lean forward on the selected item. If the question is 'Do you want vanilla, chocolate or strawberry?' (a closed set) and the answer is 'I want strawberry,' it is 'strawberry' that is 'selected' or contrasted with the other items. When 'replacing' focus is involved ('chocolate' not 'strawberry'), a lean forward is used to mark the correct response 'chocolate' and lean backward is used to mark the rejected response 'strawberry.' When two items in the same sentence are contrasted with each other ('and/or/but'), 'parallel' focus is involved and ASL uses left/right leans as well as forward/backward leans.

Syntactic Mechanisms of Focus Marking

Contrastive focalization ('topicalization') is the movement of a constituent to sentence initial position for purposes of contrasting it with a previously mentioned item. Aarons (1994) gives example (2):

(2) $\underline{\quad\quad t}$
JOHN$_i$ NOT-LIKE JANE. MARY$_j$, HE$_i$ LOVES Ø$_j$
'John doesn't like Jane. It's Mary he loves.'

Another syntactic focus construction is the cleft ('It was a new sweater that Kio gave Mia for her birthday'). ASL uses the focus sign THAT in the cleft, with nonmanual marking (brow raise) on the focused nominal ('a new sweater'), which must precede THAT. When the sequence THAT NP does occur, its interpretation is purely demonstrative ('that man'), and no brow raise is used.

Languages also have syntactic constructions that put words or phrases in focus, such as the wh-cleft ('What Kio gave Mia for her birthday was a new sweater'). The wh-cleft (so-called 'rhetorical question') is particularly useful for focusing large constituents ('sterilize surgeon's tools'):

(3) $\underline{\quad\quad\quad\quad\quad\quad\quad\quad br}$
ELLEN WORK DO++ WHAT, CLEAN
STERILIZE SURGEON POSSESSIVE
TOOLS
'What Ellen does for a living is sterilize surgeon's tools.'

Language Typology for Focus

When only part of the sentence is in focus, some languages may move the prominence marking to the focused item ([+plastic], Vallduví, 1991, 1995). English is plastic in this sense, as seen in (4), where bold indicates prominence:

(4a) Juan saw Mariko **leave** the party early.
(4b) Juan saw **Mariko** leave the party early.

In contrast, nonplastic languages, such as Catalan, have reserved locations for focus, usually in sentence initial, preverbal, or final position. The word order may be changed in order to put different focused items in the reserved position. In ASL, the wh-cleft puts the focused material in final position and uses brow raise on the nonfocused part (5) (Wilbur, 1997, 1999).

(5) $\underline{\quad\quad\quad\quad\quad\quad\quad\quad br}$
(i) HELENA SEE KIM PUT BOOK WHERE, TABLE
'The place where Helena saw Kim put the book was the table.'
$\underline{\quad\quad\quad\quad\quad\quad\quad\quad br}$
(ii) HELENA SEE KIM PUT-ON-TABLE WHAT, BOOK
'What Helena saw Kim put on the table was the book.'

br
(iii) HELENA SEE BOOK PUT-ON-TABLE WHO, KIM
'The person who Helena saw put the book on the table was Kim.'

br
(iv) HELENA SEE KIM DO++, BOOK PUT-ON-TABLE
'What Helena saw Kim do was put the book on the table.'

Common Sign Language Structure for Emphasis

Finally, linguistic prominence for 'emphasis' can be separated from focus. While focused items may also be emphasized, not all emphasized items are focused. SLs frequently have a process of 'copying' or 'doubling' certain lexical categories, including modals, negation, wh-words, subject pronouns, quantifiers, and numerals. Such doubling of signs often leads nonsigners to erroneously conclude that sign languages are just repetitive gestures with no systematic structure. But typically, a doubled item will occur sentence initially or in its in situ position, and the double will occur sentence finally. Items such as these are not new information or in focus. The repetition of them by doubling serves to emphasize them as important (but not as new) (Petronio, 1993).

Sign Language: History

B Woll, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Sign languages for the most part are examples of languages that have only emerged during the past 300 years. Just as all languages need a community of users, sign languages need a Deaf community. Deaf communities can only exist where there is a large enough concentration of deaf people (Woll and Ladd, 2003). In Europe, this only happened with the development of large towns during the industrial revolution. Before that, signers were scattered across villages and small towns and any signing must have been widely varied. The development that triggered the creation of large Deaf communities and sign languages as we know them today came when schools were set up for deaf children, starting in the late 18th century in Europe. At these schools, children were able to use a single form of a language, developed from the signed languages that were being used by educators. In many countries, education for deaf children has only recently begun and in turn has provided an environment in which sign language can develop. Linguists (e.g., Kegl *et al.*, 1999) have described how the establishment of the first school for deaf children in Nicaragua in the 1980s led to the beginnings of a national sign language.

Counts of the world's languages almost always exclude sign languages. This may be because of the relative newness of sign languages. Many people still mistakenly believe that sign languages are simply forms of spoken languages. Other people do not consider sign languages to be languages at all but merely nonlinguistic systems of gesture and pantomime. All these factors may explain why sign languages have been ignored, along with many spoken languages of disempowered communities.

The Ethnologue database, however, does include sign languages. It lists 103 known sign languages. This figure almost certainly underestimates the number of sign languages in the world, but it is an initial figure with which to work.

History of the Modern Sign Languages

One of the great achievements of comparative linguistics during the past 200 years has been the construction of language 'family trees.' Using clues from similar words and grammars and available knowledge of a language's history, linguists have placed languages into families and described their relationships to each other. The relationships of sign languages can also be traced, but the relationships are different from those of spoken languages. Spoken languages are believed not to arise independently, spontaneously, and rapidly. In general, the spoken languages of today are all assumed to have histories of many thousands of years. Sign languages, on the other hand, clearly arise spontaneously and independently in many areas of the world.

Although we cannot divide sign languages into families in the same way that we can examine spoken languages, we can, nonetheless, find patterns and relationships between sign languages. Specifically, we can see how both world politics and situations specific to the Deaf community, especially education and other 'welfare' arrangements, affect sign languages.

Glottochronological techniques have been applied to sign language to explore historical relationships. The greater the percentage of similar words, the more likely that the two language variants are mutually intelligible and considered the same language. The strength of the glottochronological approach is that it is free from social attitude judgments. However, there are problems with this approach. Basic word lists may be inappropriate for modern sign languages in the developed world and often include words that we might expect to be similar in sign languages because of the use of visually motivated signs, such as DRINK.

It is important to remember that glottochronological comparisons of sign languages use a very different scale from comparisons of spoken languages. The spoken languages cited in most studies are known to have been in existence for thousands of years, but most sign languages have only existed for centuries at most, and in some cases only decades. Sign languages for the most part are examples of languages that have only emerged during the past 300 years. Just as all languages need a community of users, sign languages need a Deaf community. Deaf communities can only exist where there is a large enough concentration of deaf people (Woll and Ladd, 2003). In Europe, this only happened with the development of large towns during the industrial revolution. Before that, signers were scattered across villages and small towns and any signing must have been widely varied. The development that triggered the creation of large Deaf communities and sign languages as we know them today came when schools were set up for deaf children, starting in the late 18th century in Europe. At these schools, children were able to use a single form of a language, developed from the signed languages that were being used by educators. In many countries, education for deaf children has only recently begun and in turn has provided an environment in which sign language can develop. Linguists (e.g., Kegl *et al.*, 1999) have described how the establishment of the first school for deaf children in Nicaragua in the 1980s led to the beginnings of a national sign language.

Counts of the world's languages almost always exclude sign languages. This may be because of the relative newness of sign languages. Many people still mistakenly believe that sign languages are simply forms of spoken languages. Other people do not consider sign languages to be languages at all but merely nonlinguistic systems of gesture and pantomime. All these factors may explain why sign languages have been ignored, along with many spoken languages of disempowered communities.

The Ethnologue database, however, does include sign languages. It lists 103 known sign languages. This figure almost certainly underestimates the number of sign languages in the world, but it is an initial figure with which to work.

History of the Modern Sign Languages

One of the great achievements of comparative linguistics during the past 200 years has been the construction of language 'family trees.' Using clues from similar words and grammars and available knowledge of a language's history, linguists have placed languages into families and described their relationships to each other. The relationships of sign languages can also be traced, but the relationships are different from those of spoken languages. Spoken languages are believed not to arise independently, spontaneously, and rapidly. In general, the spoken languages of today are all assumed to have histories of many thousands of years. Sign languages, on the other hand, clearly arise spontaneously and independently in many areas of the world.

Although we cannot divide sign languages into families in the same way that we can examine spoken languages, we can, nonetheless, find patterns and relationships between sign languages. Specifically, we can see how both world politics and situations specific to the Deaf community, especially education and other 'welfare' arrangements, affect sign languages.

Glottochronological techniques have been applied to sign language to explore historical relationships. The greater the percentage of similar words, the more likely that the two language variants are mutually intelligible and considered the same language. The strength of the glottochronological approach is that it is free from social attitude judgments. However, there are problems with this approach. Basic word lists may be inappropriate for modern sign languages in the developed world and often include words that we might expect to be similar in sign languages because of the use of visually motivated signs, such as DRINK.

It is important to remember that glottochronological comparisons of sign languages use a very different scale from comparisons of spoken languages. The spoken languages cited in most studies are known to have been in existence for thousands of years, but most sign languages have only existed for centuries at most, and in some cases only decades. The degree

of similarity seen between languages because of visual motivation in signs also makes it necessary to shift the time scale devised for calculating differences between spoken languages.

Woodward (1978) applied a glottochronological analysis to American Sign Language (ASL) and French Sign Language (LSF), finding a similarity score of 60%. Given that historical records demonstrate that ASL as we know it was only formed after LSF was introduced to America in 1816, 60% is a very low figure (this figure would be consistent with two spoken languages that had diverged at least 1700 years ago). Woodward concluded that ASL must have mixed with other sign languages that were already used in America and must be some sort of creole.

Kyle and Woll (1985) examined British Sign Language (BSL), Sign Language of the Netherlands (SLN), Italian Sign Language (LIS), and Walloon (Francophone Belgian) Sign Language. They deliberately chose these because they were not believed to be related to each other. This appeared to be borne out by data from terms for family members, which are often similar in related languages. When Kyle and Woll examined signs for family members, they found no similarities. Yet more than 40% of the signs in the four languages were closely similar or identical. The researchers noted that this figure would be remarkable in unrelated spoken languages and suggested that this high degree of similarity was caused by the presence of visually motivated (iconic) signs in the languages that exhibited similarity independently of historical links. This feature of sign languages will continue to cause problems for the classification of sign languages, unless such examples can be factored out.

McKee and Kennedy (1998) compared ASL, Auslan, New Zealand Sign Language (NZSL), and BSL using a modified version of the Swadesh list of vocabulary items. They found that Auslan, NZSL, and BSL had a similarity of approximately 80% when using the Swadesh list. However, this fell to approximately 64% when they used a semirandom selection of signs. They found that Auslan and NZSL were more similar to each other than they were to BSL. They also found that many Auslan signs that were 'different' from BSL were actually similar to old BSL signs that are no longer commonly in use in Britain. This demonstrates the dangers of comparing a small list of signs and the importance of the need to recognize that some dialects of different sign languages may be more similar to each other than other dialects.

The sign languages of Germany, Austria, and Hungary are closely related, as part of the legacy of the Hapsburg Empire. Teachers of the deaf were trained in Germany and they influenced Deaf communities throughout that empire (McCagg, 1993). Britain's history of empire and commonwealth has meant that sign languages used thousands of miles apart may be very similar. Deaf children from all over the British Empire were educated in Britain and returned to their own countries, bringing their signs with them. Even more significantly, deaf adults joined other immigrants to the colonies, bringing BSL. Consequently, today Auslan, NZSL, and certain dialects of Indian and South African sign languages are intelligible to BSL users.

The first Irish deaf school was set up by a British man in Dublin at the start of the 19th century, and for several decades BSL was used by the pupils. Today, despite subsequent radical changes in the Irish deaf education system that resulted in Irish Sign Language (ISL) being more closely related to LSF, some ISL signs are similar to BSL. Much of this may be accounted for by later borrowing, but other signs are considered by ISL signers to be well-established signs that are not seen as loans (Matthews, 1996). As a result of the Japanese occupation of Taiwan, some dialects of sign language in Taiwan are very similar to Japanese Sign Language. Since Japanese withdrawal, however, and with the influx of large numbers of people from the Chinese mainland, another form of Taiwanese Sign Language has developed that is more similar to the sign language used in Shanghai (Ann, 1998).

World politics has also influenced Israeli Sign Language. In the early years of Jewish settlement in Palestine, most deaf people came from Germany, Hungary, and other Central European countries. These deaf people were relatively well educated and were fluent signers. They had considerable influence in the education system and in the production of the Israeli Sign Language dictionary. Israeli Sign Language today contains many signs similar to those in German Sign Language (Namir *et al.*, 1979).

Educational Systems

Another very strong influence on sign languages has come not from political domination but from educational systems being shared between nations. Frequently, educators from one country have had a religious or missionary agenda when bringing education and their own sign language to other countries.

The language that has had the most profound influence on other sign languages, especially in Europe and North America, has been LSF. The powerful influence of LSF over the world's sign languages should not be underestimated. Influence from LSF can be seen clearly in ISL (Burns, 1998), ASL (Lane, 1984), Russian Sign Language (Mathur *et al.*, 1998), and on some dialects of BSL (particularly where BSL

Figure 1 Proposed relationship of 'North-West European' sign languages. After Anderson (1979), cited in Sutton-Spence *et al.* (2001).

has been influenced by ISL). In each case, educators were influenced by the French deaf education system and brought LSF back to their own countries. Other sign languages have also had this sort of influential role. For example, Swedish Sign Language has influenced Portuguese Sign Language through its use of the manual alphabet, after a Swedish educator helped to found a deaf school in Portugal.

ISL, originally heavily influenced by LSF, has also had considerable impact on sign languages throughout the world. Irish nuns and Christian Brothers have taught in Catholic schools for deaf children in countries including India, South Africa, and Australia, and the influence of ISL is noticeable in the sign languages in these countries (Aarons and Akach, 1998).

ASL, also heavily influenced by LSF in the past, now has a major impact on sign languages throughout the world. Gallaudet University offers scholarships to foreign deaf students who take ASL back to their own countries. The United States has been especially generous in providing teacher training for teachers in many Third World countries. Andrew Foster, a deaf African American, led a movement for the establishment of schools in African countries where ASL was introduced as the language of tuition (Lane *et al.*, 1996). In Nigeria, ASL taught in schools is mixing with the indigenous sign languages (Schmaling, 2000). Even when ASL is not deliberately taught in schools in other countries, the presence of fluent signers of ASL can exert an influence. The U.S. presence in Nicaragua has led to influence of ASL on Nicaraguan Sign Language. Scandinavian sign languages have also influenced African and Asian sign languages as aid programs use foreign nationals to help set up schools in developing countries.

Anderson (1979) is one of the few linguists to have attempted to create family trees for sign languages (Figure 1).

In the absence of written or pictorial records, it is unlikely that we will be able to discover earlier data on any of the European sign languages. However, with the recent growth of comparative and cross-linguistic research on sign languages from Asia and Africa, and our increased understanding of the circumstances in which sign languages develop, it may be possible to expand our understanding of the history of sign languages.

The first modern linguistic analysis of a signed language was published in 1960: *Sign language structure: an outline of the visual communication systems of the American deaf*. The author was William C. Stokoe, Jr. (1919–2000), a professor of English at Gallaudet College, Washington DC, the only college for the deaf in existence at that time. To be sure, Stokoe was not the first scholar to take an interest in signed languages; during the 18th and 19th centuries, sign language and deafness were the subject of a number of learned reflections in France and England. Unlike the work of Stokoe (and those that followed him), the early works focused not on the linguistic aspects of signed languages, but rather on nonlinguistic issues such as the use of signs in teaching the deaf and the potential for sign to become a universal language. While this article primarily focuses on the history of modern linguistic research on the natural signed languages of the deaf, I shall begin with a brief discussion of some of the important works that predate the work of William Stokoe.

The Prehistory of Sign Language Linguistics

The history of modern sign language linguistics is, in many respects, closely tied to the institutional education of the deaf, which itself began in the late 1760s when Abbé Charles Michel de l'Épee (1712–1789) founded the first school for the deaf in Paris, France. De l'Épee's *L'institution des sourds et muets, par la voie des signes méthodiques* (1776) outlines his method for teaching the deaf through the use of methodical signs, manual gestures that represented specific aspects of French grammar. While this method relied, for the most part, on signs that were either adapted from natural signs or invented (and therefore served as a form of manual French), de l'Épee and his followers understood the value of manual communication as an educational tool and took a serious interest in the natural language (i.e., French Sign Language) used among the deaf (see Seigel, 1969). One of de l'Épee's followers, Auguste Bébian (1789–1839), was an avid supporter of the use of French Sign Language in the classroom. Bébian's most influential work, the one that relates most directly to modern linguistic analyses of signed languages, is his 1825 *Mimographie: essai d'écriture mimique, propre à régulariser le langage des sourds-muets*. In this work, Bébian introduces a sign notation system that is based on three cherological (phonological) aspects: the movement, the *instruments du geste* (the means of articulation), and the *points physionomiques* (applying mainly to aspects of facial expression) (cf., Fischer, 1995). Using this notation system, Bébian presents a dictionary of signs that is organized in such a way as to facilitate independent learning on the part of the students. In addition to serving as an

The first modern linguistic analysis of a signed language was published in 1960: *Sign language structure: an outline of the visual communication systems of the American deaf*. The author was William C. Stokoe, Jr. (1919–2000), a professor of English at Gallaudet College, Washington DC, the only college for the deaf in existence at that time. To be sure, Stokoe was not the first scholar to take an interest in signed languages; during the 18th and 19th centuries, sign language and deafness were the subject of a number of learned reflections in France and England. Unlike the work of Stokoe (and those that followed him), the early works focused not on the linguistic aspects of signed languages, but rather on nonlinguistic issues such as the use of signs in teaching the deaf and the potential for sign to become a universal language. While this article primarily focuses on the history of modern linguistic research on the natural signed languages of the deaf, I shall begin with a brief discussion of some of the important works that predate the work of William Stokoe.

The Prehistory of Sign Language Linguistics

The history of modern sign language linguistics is, in many respects, closely tied to the institutional education of the deaf, which itself began in the late 1760s when Abbé Charles Michel de l'Épee (1712–1789) founded the first school for the deaf in Paris, France. De l'Épee's *L'institution des sourds et muets, par la voie des signes méthodiques* (1776) outlines his method for teaching the deaf through the use of methodical signs, manual gestures that represented specific aspects of French grammar. While this method relied, for the most part, on signs that were either adapted from natural signs or invented (and therefore served as a form of manual French), de l'Épee and his followers understood the value of manual communication as an educational tool and took a serious interest in the natural language (i.e., French Sign Language) used among the deaf (see Seigel, 1969). One of de l'Épee's followers, Auguste Bébian (1789–1839), was an avid supporter of the use of French Sign Language in the classroom. Bébian's most influential work, the one that relates most directly to modern linguistic analyses of signed languages, is his 1825 *Mimographie: essai d'écriture mimique, propre à régulariser le langage des sourds-muets*. In this work, Bébian introduces a sign notation system that is based on three cherological (phonological) aspects: the movement, the *instruments du geste* (the means of articulation), and the *points physionomiques* (applying mainly to aspects of facial expression) (cf., Fischer, 1995). Using this notation system, Bébian presents a dictionary of signs that is organized in such a way as to facilitate independent learning on the part of the students. In addition to serving as an

educational tool, the *Mimographie* served as a way of standardizing and recording FSL signs, which Bébian hoped would lead to further development and serious study of the language itself (see Fischer, 1993). Although the primary focus of Bébian's work was not exclusively linguistic, his *Mimographie* is a significant contribution to the linguistic study of signed languages in that his notation system represented a phonological approach to the analysis of signs.

A contrasting approach to educating the deaf was adopted in Germany by Samuel Heinicke (1723–1790), considered by many to be the father of oral deaf education. Unlike de l'Épee and his colleagues in France, Heinicke's primary concern was the integration of deaf children into hearing society, a goal best accomplished, he believed, by prohibiting the use of manual signs and instead focusing on speech and speech reading. These two distinct educational philosophies (manualism and oralism) spread throughout Europe in the 18th and 19th centuries; the manual approach of de l'Épee took hold in areas of Spain, Portugal, Italy, Austria, parts of Scandinavia, French Switzerland, and Russia, while the oral approach of Heinicke was adopted by educators in many German-speaking countries and parts of Scandinavia. In the UK, early efforts at institutional education of the deaf favored a 'combined' approach that utilized speech and sign (see Kyle and Woll, 1985), but a strictly oral approach eventually took hold here as well.

In 1815, the American Thomas Hopkins Gallaudet (1787–1851) traveled to Europe and spent time at the Paris school observing and learning the manual educational techniques used there. Gallaudet returned to America and brought with him a deaf Frenchman, Laurent Clerc; together the two men established, in 1817, the first American school for the deaf in Hartford, Connecticut. Clerc's French Sign Language, as well as certain aspects of the methodical signing, was introduced into the school's curriculum, where it mingled with the gestural systems already in use by the deaf children and eventually evolved into what is now known as American Sign Language (ASL). ASL flourished in American schools for the deaf until the middle of the 1800s, at which time interest in the oral method of education grew.

An important event in the history of deaf education, and therefore also in the history of sign language research, was the Second International Congress on Education of the Deaf, held in Milan, Italy, in 1880. At this congress, a resolution was passed stating that oral methods of educating the deaf were superior to manual methods, and in subsequent years there were drastic changes in political and public policy concerning the deaf in Europe. The consensus now was to promote oralism, and signing in the schools was banned. Though the effects of the Milan Congress were felt most directly in European schools for the deaf, the oralist approach to the education of the deaf eventually took hold in America as well and there was a marked decline in the use of ASL. Within the United States, oralism enjoyed widespread acceptance through the 1960s and into the early 1970s.

This shift toward exclusively oral education of the deaf led, quite directly, to signed languages being considered devoid of value, a sentiment that persisted for most of the following century. Had the manual tradition of de l'Épee and his followers not been effectively stamped out by the Milan resolution, interest in signed languages would surely have persisted, and might even have led to earlier recognition of signed languages as full human languages, worthy of linguistic study. As it was, in the first half of the 20th century, the prevailing view of signed languages, both in the field of education and in the field of general linguistics, was that they were little more than crude systems of gestures. Leonard Bloomfield, for example, characterized signed languages as "merely developments of ordinary gestures" in which "all complicated or not immediately intelligible gestures are based on the conventions of ordinary speech" (Bloomfield, 1933: 39). The "deaf-and-dumb" language was, to Bloomfield, most accurately viewed as a "derivative" of language.

Early Sign Language Research in North America

The Pioneering Work of William C. Stokoe

In 1955, William Stokoe accepted a job in the English Department at Gallaudet College (now Gallaudet University). He had received his Ph.D. in English from Cornell University in Ithaca, NY, in 1946, and in the years directly prior to his arrival at Gallaudet, Stokoe had been working on various problems in Old and Middle English, and had come across George Trager and Henry Lee Smith's *An outline of English structure* (1951). The procedural methods for linguistic analysis advocated by Trager and Smith made a lasting impression on Stokoe. As he was learning the basics of sign communication at Gallaudet and, more importantly, watching his deaf students sign to each other, Stokoe noticed that the signs he was learning lent themselves to analysis along the lines of minimal pairs (see Stokoe, 1979). This initial observation led Stokoe to explore the possibility that signs were not simply iconic pictures drawn in the air with the hands, but rather were organized symbols composed

of discrete parts. Stokoe spent the summer of 1957 studying under Trager and Smith at the LSA-sponsored Linguistics Institute held in Buffalo, NY, and then returned to Gallaudet and began working on a structural linguistic analysis of American Sign Language. In April of 1960, *Sign language structure* appeared in the Occasional Papers of the journal *Studies in Linguistics*, published by the Department of Anthropology and Linguistics at the University of Buffalo, New York.

There are two main contributions of this first modern linguistic analysis of a signed language. First, Stokoe presented an analysis of the internal structure (i.e., the phonology) of individual signs; the three primary internal constituents that Stokoe identified are the tabula (position of the sign), the designator (hand configuration) and the signation (movement or change in configuration). Stokoe's analysis of the abstract sublexical structure of signs illustrated that the signs of signed languages were compositional in nature, and were quite unlike nonlinguistic gestures. The second major contribution of the 1960 monograph was the transcription system Stokoe proposed (subsequently referred to as Stokoe notation). Prior to the publication of the 1960 monograph, there existed no means of writing or transcribing the language used by members of the American deaf community; individual signs had been cataloged in dictionaries through the use of photographs or drawings, often accompanied by written English descriptions of the gestures. Stokoe notation provided a means of transcribing signs, and in so doing helped illuminate the internal structure of the language.

In the years directly following the publication of the monograph, Stokoe continued developing his analysis of ASL. With the help of two deaf colleagues, Carl Croneberg and Dorothy Casterline, Stokoe published the first dictionary of ASL in 1965, *A dictionary of American Sign Language on linguistic principles* (*DASL*) (Stokoe *et al.*, 1965). It is an impressive work, cataloging more than 2000 different lexical items and presenting them according to the linguistic principles of the language. Stokoe's two early works formed a solid base for what was to become a new field of research: Sign Language Linguistics.

For the most part, Stokoe's initial work on the structure of ASL was not well received within the general linguistics community (see McBurney, 2001). The message contained within the monograph – that signed languages are true languages – stood counter to the intellectual climate within the field of linguistics at that time. In the years prior to the publication of *Sign language structure*, language was equated with speech, and linguistics was defined as the study of the sound symbols underlying speech behavior. This view of linguistics, and of what constitutes a language, was not easily changed. Furthermore, Stokoe's analysis of ASL was nested within a structuralist framework, a framework that soon fell out of favor. The 1957 publication of Noam Chomsky's *Syntactic structures* marked the beginning of a new era of linguistic theory, where the focus shifted from structural analysis to an explication of the generative capacities of grammar. Because Chomsky's emphasis on grammar as a cognitive capacity was nowhere to be found in the work of Stokoe, it is not entirely surprising that Stokoe's monograph received little attention from linguists of the day.

Just as Stokoe's early work was not well received by linguists, the analysis of ASL along linguistic lines was not something that was readily accepted by deaf educators and related professionals. Though ASL had been used by students outside the classroom all along, oralism had been standard practice in most schools for many years, and Stokoe's seemingly obscure and technical analysis of signs did not change that overnight. In the years directly following the publication of Stokoe's monograph, educators still did not consider the sign language to be a real language worthy of study, and any efforts to utilize signing in the classroom would interfere, they claimed, in the education of deaf students. It was not until the late 1960s and early 1970s that this began to change; around this time many educators, frustrated by the failure of oral methods, began using a combined approach where sign and speech were used together. This period also saw a change in the overall perception of deaf people in America; a changing attitude toward disabled Americans and an increasing articulateness and visibility of deaf leaders brought about a new appreciation for and acceptance of the language of the deaf community. Throughout the 1970s and 1980s, the combined method (a version of which was termed total communication) came to be used in most schools, representing a marked change from strictly oral education. In more recent years, the bilingual approach to the education of the deaf, in which ASL is considered the first language of the deaf and English is learned as a second language, primarily through reading and writing, has gained popularity.

The Development of the Discipline

Even though Stokoe's early work was not acknowledged or accepted by either linguists or educators, Stokoe continued his research on the linguistics of ASL and inspired many others to do the same (see Armstrong *et al.*, eds. 2002). Before long, scholars recognized that ASL evidenced the duality of

patterning that is characteristic of natural languages, and that it therefore warranted the same types of scientific investigation as spoken languages.

In 1970, the Laboratory for Language and Cognitive Studies (LLCS) was established at the Salk Institute for Biological Studies in San Diego, under the directorship of Ursula Bellugi (the laboratory's name was eventually changed to the Laboratory for Cognitive Neuroscience). In the years following its founding, this laboratory hosted a number of researchers who have conducted an impressive amount of research on the grammar, acquisition, and processing of ASL, both at the LLCS and at other institutions across North America (among them are Robbin Battison, Penny Boyes Braem, Susan Fischer, Nancy Frishberg, Harlan Lane, Ella Mae Lentz, Don Newkirk, Elissa Newport, Patricia Siple, Ted Supalla, Scott Liddell, Richard Meier, Geoffrey Coulter, David Corina, and Karen Emmorey). Also in San Diego, graduate students of linguistics and psychology at the University of California researched various aspects of ASL structure; the most well known, perhaps, was Carol Padden, a deaf linguist whose 1983 Ph.D. dissertation (published in 1988) was and continues to be an influential study of the morphosyntax of ASL.

In 1971, the Linguistics Research Lab was established at Gallaudet College. Stokoe served as its director and continued to work, along with a number of other researchers, on the linguistic analysis of ASL. Although the LRL closed its doors in the late 1970s, many researchers who got their start there went on to do important work in the field (among them were Laura Petitto, Carol Padden, James Woodward, and Harry Markowicz). The following year, 1972, Stokoe began publishing the quarterly journal *Sign Language Studies*. Although publication was briefly suspended in the 1990s, for over 30 years *Sign Language Studies* (currently published by Gallaudet University Press and edited by David Armstrong) has served as a primary forum for the discussion of research related to signed languages. The same year also saw the publication of one of Stokoe's later influential works, *Semiotics and human signed languages* (Stokoe, 1972).

The first linguistics Ph.D. dissertation on ASL was written at Georgetown University in 1973 by James Woodward, one of the researchers who had worked with Stokoe in the Linguistics Research Laboratory at Gallaudet. Since that time, well over 200 theses and dissertations have been written on ASL, representing all the major subfields of linguistic analysis. Also in 1973, a section on sign language was established at the annual conference of the Linguistic Society of America. At the 1973–1974 LSA meeting, members of the LLCS presented papers on the phonological structure of ASL and, henceforth, research on ASL began to have an impact on the general linguistic community (Newport and Supalla, 2000).

In 1974, the first conference on sign language was held at Gallaudet, and in 1979 the Department of Linguistics was established at Gallaudet University. At present, there are several other linguistics departments around the United States that have a particular focus on ASL, including Boston University, University of Arizona, Rutgers University, University of Rochester, University of California at San Diego, University of Texas at Austin, University of New Mexico, and Purdue University.

While much of the initial work on ASL focused on the phonological structure of ASL, throughout the 1970s and 1980s an increasing number of American researchers published works that contributed to a broader understanding of the linguistic structure of ASL. Among the areas explored during this period were the following: complex word structure, particularly verbal constructs (Fischer, 1973; Padden, 1983); morphological processes (Supalla and Newport, 1978); verbs of motion and location (Supalla, 1983); and syntactic structure, including nonmanual markers (Liddell, 1980).

Aside from Stokoe's 1960 monograph, the single most influential work in the discipline of sign language linguistics, and, more specifically, in the acceptance of signed languages as real languages, worthy of linguistic study, was Edward Klima and Ursula Bellugi's *The signs of language (SOL)* (Klima and Bellugi, 1979). *SOL* had begun as a collection of working papers at the Salk Institute's LLCS, but was developed into a full-length book and published by Harvard University Press in 1979. Although this volume was, and still is, referred to as the Klima and Bellugi text, it was, in fact, a summary of research that had been conducted by a number of scholars throughout the 1970s, all of whom worked with Bellugi at Salk. In addition to discussing the internal structure of signs, *SOL* contained analyses of, among other things, the origin and development of ASL, historical changes in the language, the nature of iconicity, the grammatical processes at work, the coding and processing of signs, and wit and poetry in ASL. The text was particularly thorough in its treatment of the various aspects of ASL morphology.

In contrast to *Sign language structure*, Klima and Bellugi's *The signs of language* was widely read by linguists as well as individuals working in related disciplines. *SOL* was, and still is, viewed as an important work, one that demonstrates that human language does not have to be spoken, and that therefore the human capacity for language is more profound that the mere capacity for vocal–auditory communication.

While the changing theoretical landscape of Stokoe's time worked against him, it worked to the advantage of Klima and Bellugi; the paradigmatic shift in linguistic theory that followed from the work of Chomsky created a new space for and interest in the study of signed languages. If the universal principles that are proposed to exist in all languages are, in fact, universal, then they should be able to account for language in another modality.

While ASL is used in much of Canada, Langue des Signes Québécoise (LSQ) is used by French deaf people throughout the country. In the late 1970s, a group of deaf researchers, headed by Paul Bourcier and Julie Elaine Roy, began working on a dictionary of LSQ at the Institut Raymond-Dewar in Montréal. Also at this time, Rachel Mayberry conducted some preliminary research on the comprehension of LSQ. In 1982, Laura-Ann Petitto established the Cognitive Science Laboratory for Language, Sign Languages, and Cognition at McGill University, in Montréal, where she investigated the linguistic structure, acquisition, and neural representation of LSQ. Fernande Charron, one of Dr. Petitto's graduate students, was actively involved in the lab's research as well. In 1988, Colette Dubuisson of Université du Québec à Montréal received a research grant from the Social Sciences and Humanities Research Council of Canada (SSHRC) and began working on the linguistics of LSQ; collaborators in this group included Robert Fournier, Marie Nadeau, and Christopher Miller.

Early Sign Language Research in Europe

The earliest work on signed communication in Europe was Bernard Tervoort's 1953 dissertation (University of Amsterdam), *Structurele analyse van visueel taalgebruik binnen een groep dove kinderen* (Structural analysis of visual language use in a group of deaf children) (Tervoort, 1954). This work has not, for the most part, been considered a modern linguistic analysis of a signed language because the signing he studied was not a complete and natural sign language; the Dutch educational system forbade the use of signs in the classroom, so most of the signs the children used were developed among the children themselves and did not, therefore, represent Sign Language of the Netherlands (SLN), a true natural signed language. Nevertheless, Tervoort treated the behavior of the children as largely linguistic in nature, and his descriptions of the signing suggest a complex structural quality.

Research on the linguistics of natural signed languages emerged later in Europe than it did in the United States. Two factors contributed to this (see *Sign Languages in Europe: History and Research*). First, European schools for the deaf maintained a strictly oral focus longer than did schools in North America; signing was discouraged, and signed languages were not understood to be languages worthy of study. Second, the rise in social status and acceptance of sign language that deaf Americans enjoyed beginning in the late 1960s was not, for the most part, experienced by deaf Europeans until later.

European sign language research began in the 1970s and became established most quickly in Scandinavia. Research on the linguistics of Swedish Sign Language began in 1975 at the University of Stockholm, Department of Linguistics, under the direction of Brita Bergman (Bergman, 1982). Other linguists involved in early work on Swedish Sign Language included Inger Ahlgren, Sten Ulfsparre, Birgitta Ozolins, Lars-Åke Wikstroem, and Lars Wallin. In neighboring Scandinavian countries, research on the structure of other signed languages was to follow. In 1979 Marit Vogt-Svendsen began working on Norwegian Sign Language at the Norwegian Postgraduate College of Special Education, near Oslo, and in 1981 Odd-Inge Schröder began a research project at the University of Oslo. Research on the structure of Finnish Sign Language was initiated in 1982, at the Department of General Linguistics at the University of Helsinki, with some of the earliest research conducted by Terhi Rissane.

In Germany, scholars turned their attention to German Sign Language (Deutsche Gebärdensprache, DGS) in 1973 when Seigmund Prillwitz, Rolf Schulmeister, and Hubert Wudtke started a research project at the University of Hamburg (Prillwitz, 1985). In 1987, Dr. Prillwitz founded the Center for German Sign Language and Communication of the Deaf at the University of Hamburg (the center has since become the Institute for German Sign Language and Communication of the Deaf). Several other researchers contributed to the early linguistic investigations, including Regina Leven, Tomas Vollhaber, Thomas Hanke, Karin Wempe, and Renate Fischer. One of the most important projects undertaken by this research group was the development and release, in 1987, of the Hamburg Notation System (HamNoSys), a phonetic transcription system developed in the tradition of Stokoe's early notation. A second major contribution is the International Bibliography of Sign Language; a searchable online database covering thousands of publications related to sign language, the bibliography is an indispensable tool for sign linguists.

Research on the structure of Danish Sign Language began in 1974, with early projects being initiated by Britta Hansen at the Doeves Center for Total Communication (KC) in Copenhagen. Dr Hansen collaborated with Kjær Sørensen and Elisabeth

Engberg-Pedersen to publish the first comprehensive work on the grammar of DSL in 1981, and since that time there has been a considerable amount of research into various aspects of DSL. The early 1970s also marked the start of research on Israeli Sign Language, with linguistic investigations and dictionary development instigated by Izchak Schlesinger, and Lila Namir.

The first linguistics Ph.D. dissertation on a European sign language (British Sign Language, or BSL) was written by Margaret Deuchar (Stanford University, California, 1978). Following this, in the late 1970s and early 1980s, there was a marked expansion of research on the linguistics of BSL (see Lee, 2005). The Edinburgh British Sign Language Research Project (1979–1984) was headed by Mary Brennan and focused primarily on developing a notation system for BSL. In 1978, the Sign Language Learning and Use Project was established at the University of Bristol; this project eventually led to the formation of the Centre for Deaf Studies (CDS) at Bristol, cofounded in 1980 by James Kyle and Bencie Woll. Early research here focused on language acquisition and coding of BSL, but before long scholars at CDS were exploring all aspects of the structure of BSL (Kyle and Woll, 1985). The Deaf Studies Research Unit at the University of Durham was established in 1982, and researchers there worked to complete a dictionary of BSL, originally begun by Allan B. Hayhurst in 1971.

In the mid 1970s, Bernard Mottez and Harry Markowicz at the Centre National de la Recherche Scientifique (CNRS) in Paris began mobilizing the French deaf community and working toward the recognition and acceptance of French Sign Language (LSF). While the initial focus here was social, research on the structure of LSF began soon after. Two of the first researchers to focus specifically on linguistic aspects of LSF were Christian Cuxac (Cuxac, 1983) and Danièle Bouvet in the late 1970s. Another important early scholar was the late Paul Jouison, who, in the late 1970s, worked with a group of deaf individuals in Bordeaux to develop a notation system for LSF, and went on to publish a number of important works.

In Italy, Virginia Volterra and Elena Pizzuto were among the first to do research on Italian Sign Language (LIS) in the late 1970s and early 1980s. Working at the CNR Institute of Psychology in Rome, these women conducted a wide range of investigations into various linguistic, psycholinguistic, educational, and historical aspects of LIS (Volterra, 1987). Also in the late 1970s, Penny Boyes-Braem, who had worked alongside Ursula Bellugi at the LLCS, started a research center in Basel, Switzerland, and began investigating the structure of Swiss–German Sign Language.

Modern linguistic research on the Sign Language of the Netherlands (SLN) began in the early 1980s. Following the publication of his 1953 thesis, Bernard Tervoort continued to publish works on language development and sign communication in deaf children, but the focus of most of his investigations was not, strictly speaking, linguistic. In 1982, the first formal sign language research group was established at the Dutch Foundation for the Deaf and Hard of Hearing Child (NSDSK), with support from Bernard Tervoort at the University of Amsterdam. The initial focus here was research into the lexicon of SLN; Trude Schermer served as the project director for the development of the first SLN dictionary, and worked in collaboration with Marianne Stroombergen, Rita Harder, and Heleen Bos. Research on various grammatical aspects of SLN was also conducted at the NSDSK, and later on at the University of Amsterdam as well.

Throughout the 1980s and 1990s, sign language research continued to flourish across much of Europe, and the number of individual researchers and research groups has grown considerably. Here the focus has been on discussing the earliest work on individual European signed languages. While some European signed languages have received more scholarly attention than others, nearly all natural signed languages found in Europe have been subject to at least some degree of linguistic investigation.

Sign Language Research in Other Parts of the World

Research on the linguistics of natural signed languages outside North America and Europe is, for the most part, less well established, though certainly underway in a number of other countries around the globe. Dictionaries have been compiled for many of these signed languages, and additional research into the linguistic structure of some has been undertaken. Here, I mention only a few. In the mid 1970s, research on Indian Sign Language was undertaken by Madan Vasishta, in collaboration with Americans James Woodward and Kirk Wilson. More recent research by Ulrike Zeshan has revealed that the sign languages of India and Pakistan are, in fact, varieties of the same language, which she terms Indo-Pakistani Sign Language (IPSL). Chinese Sign Language was also the subject of scholarly interest in the mid 1970s, with initial research conducted by Shun-Chiu Yau. The late 1970s and early 1980s saw beginning research on a number of other signed languages, including Taiwanese Sign Language (Julia Li-mei Chen and Wayne Smith) and Brazilian Sign Language (Lucinda Ferreira-Brito). With the exception of Brazilian Sign Language, studies

of the sign languages of South America were not undertaken until the 1990s. Finally, research on the lexicon and structure of Australian Sign Language (Auslan) began in the mid 1980s, with Trevor Johnston's 1989 Ph.D. dissertation (University of Sydney) (Johnston, 1989) serving as the first full-length study of the linguistics of Auslan.

Establishment of Sign Language Linguistics

One indication of Sign Language Linguistics having become a mature field of scholarly endeavor is its professionalization. There have been no fewer than four different series of conferences or symposia dealing with sign language linguistics, nearly all of which were followed by the publication of conference proceedings. The earliest of these was the National Symposium on Sign Language Research and Training. Primarily a meeting of American researchers and educators, the NSSLRT held its first symposium in 1977 (Chicago, IL), and others followed in 1978 (Coronado, CA), 1980 (Boston, MA) and 1986 (Las Vegas, NV). In 1979, the first International Symposium on Sign Language Research was held in Stockholm, Sweden. The ISSLR held a total of five symposia, with additional meetings in 1981 (Bristol, England), 1983 (Rome, Italy), 1987 (Lappeenranta, Finland), and 1992 (Salamanca, Spain). In contrast to the ISSLR, which brought together researchers from North America and Europe, the European Congress on Sign Language Research (ECSL) focused on research being conducted on European sign languages. Four meetings were held by this congress: 1982 (Brussels, Belgium), 1985 (Amsterdam, The Netherlands), 1989 (Hamburg, Germany), and 1994 (Munich, Germany). Finally, the International Conference on Theoretical Issues in Sign Language Research (TISLR) first convened in 1986 (Rochester, NY), and was followed by (largely) biannual conferences in 1988 (Washington, DC), 1990 (Boston, MA), 1992 (San Diego, CA), 1996 (Montreal, Canada), 1998 (Washington, DC), 2000 (Amsterdam), and 2004 (Barcelona, Spain). While both European and North American researchers continue to hold smaller research meetings and seminars, TISLR has become the primary international conference for sign language researchers.

The International Sign Linguistics Association (ISLA) was founded in 1987 to encourage and facilitate sign language research throughout the international community. Three publications have come out of this organization: the newsletter *Signpost*, which first appeared in 1988, became a quarterly periodical in the early 1990s and was published by ISLA until 1995; *The International Journal of Sign Linguistics* (1990–1991); and *The International Review of Sign Linguistics* (1996, published by Lawrence Erlbaum Associates). In 1998 John Benjamins began publishing the peer-reviewed journal *Sign Language and Linguistics*, with Ronnie Wilbur serving as the general editor.

In 1989 Signum Press was created; an outgrowth of the Institute for German Sign Language and Communication of the Deaf at the University of Hamburg, Signum Press publishes a wide range of books and multimedia materials in the area of sign language linguistics, and also publishes *Das Zeichen*, a quarterly journal devoted to sign language research and deaf communication issues. Finally, the online discussion list, SLling-L, has been up and running since the early 1990s and is devoted to the discussion of the linguistic aspects of natural signed languages. With a subscription rate of nearly 400, this electronic forum has become a central means of facilitating scholarly exchange and, thus has played an important role in the growth of the discipline of sign language linguistics.

Overall Trends in the Field

During the early years of sign language linguistics, much of the research focused on discovering and describing the fundamental structural components of signed languages, most particularly at the level of phonology, but morphology and syntax as well. Such discoveries served as proof that, contrary to what had been previously assumed, signed languages were legitimate human languages, worthy of linguistic analysis. Early works tended to stress the arbitrariness of signs and highlight the absence of iconicity as an organizing principle underlying signed languages, and features that were markedly different from spoken languages were not often addressed. The early research revealed that signed languages are structured, acquired, and processed (at the psychological level) in ways that are quite similar to spoken languages. With advances in technology, researchers eventually discovered that largely identical mechanisms underlie the neurological processing of languages in the two modalities.

In later years, once the linguistic status of signed languages was secure, researchers eventually turned their attention to some of the more unusual aspects of signed languages, such as the complex use of space, the importance of nonmanual components, and the presence of both iconicity and gesture within signed languages. In recent years, there has been an increased interest in questions concerning sign language typology; cross-linguistic studies have revealed that signed languages are remarkably similar in certain respects (for example, in the use of space in verbal and aspectual morphology). This has led

researchers to examine more seriously the effects that language modality might have on the overall structure of language (see, for example, papers in Meier *et al*., 2002). Crosslinguistic research on an increasing number of natural signed languages has been facilitated by the development of multimedia tools for the collection, annotation, and dissemination of primary sign language data (most notably SignStream, a database tool developed at Boston University's American Sign Language Linguistic Research Project (ASLLRP), under the direction of Carol Neidle).

One additional research project deserves mention. Since the mid 1980s, linguist Judy Kegl and colleagues have been studying the newly formed deaf community in Nicaragua, and have essentially witnessed the birth of a new language: Nicaraguan Sign Language (NSL). In this living laboratory, researchers have been able to document the unfolding of language within a population of deaf children over time. Results of recent studies indicate that, between generations of signers, the language has evolved from home sign, through a stage of pidginization, and finally into NSL. The full-blown language arose rather abruptly when very young children began to restructure and regularize the variable and impoverished sign pidgin. This unusual project highlights the extent to which the study of signed languages has broadened and deepened our understanding of the nature and structure of human language.

Locating Sign Language Interpreting

Since the groundbreaking work of William C. Stokoe (1960), it has become widely recognized that natural sign systems are amenable to linguistic description in parallel with spoken languages and are therefore identifiable as complete, independent languages (e.g., Sutton-Spence and Woll, 1999; Lucas, 2001; Liddell, 2003). Sign language (SL) interpreting therefore aligns analytically, professionally, and pedagogically with other forms of interpreting, fitting the prototype formulated by Franz Pöchhacker: "Interpreting is a form of Translation in which a first and final rendition in another language is produced on the basis of a one-time presentation of an utterance in a source language" (2004: 11). In the case of SL interpreting, one of the languages is typically spoken, and one signed. SL interpreting is exceptional in requiring the transfer of meaning between language *modalities* (visual-gestural and oral-aural) as well as languages.

SL interpreting differs in several key ways, however, from those forms dominant within the early years of interpreting studies (where analysis often centered upon international gatherings, war crimes trials, and the like). Firstly, its norms correspond much more closely to those of community interpreting (CI) than to those of conference interpreting (Mikkelson, 1999). In particular, since SLs have occupied the position of 'minority languages' (in socioeconomic and geopolitical terms), issues of relative power and status – of the interpreters and of their clients, expressed through their languages – have been prominent in the theoretical development of the field. Furthermore, like CI, the work of SL interpreters is most commonly bilateral; however, the biological inaccessibility of spoken utterances to Deaf people presages a profession staffed almost exclusively by people whose dominant language is spoken. This has resulted in a highly imbalanced workforce wherein issues of cultural allegiance therefore become intense (Mindess, 1999). Secondly, the nature of the language pairs present in SL interpretations makes simultaneous, rather than consecutive, interpreting by far the more typical form, largely because the linguistic interference effects are minimized when the languages are produced and received through entirely different channels. The tacit expectation is therefore likely to be that SL interpreters will work in the simultaneous mode, despite the fact that they will be transferring meaning between modalities as well as languages – twice the task, to be done in a fraction of the time! Finally, it is necessary to distinguish between SL interpreting and transliteration: the latter term – particularly associated with the United States (Winston, 1989) – refers to the transfer of meaning from a spoken language to a manually coded form of the same language (e.g., English to Signed English). The linguistic status of these forms remains in dispute (Lucas, 2001), but either they are essentially English – in which case, no interpretation, in the sense defined here earlier, is taking place – or they fall within the range of 'natural' SL variation – in which case no exceptional descriptive apparatus is required to account for SL interpreting using such forms.

Historical Background

Historically, SL interpreting of some description has doubtless existed wherever communication has been mediated between signing and nonsigning people. The hearing children of Deaf, signing parents, becoming fluent bilinguals through natural language transmission, were most likely to act as interpreters (Preston, 1994). This task began to receive formal

Locating Sign Language Interpreting

Since the groundbreaking work of William C. Stokoe (1960), it has become widely recognized that natural sign systems are amenable to linguistic description in parallel with spoken languages and are therefore identifiable as complete, independent languages (e.g., Sutton-Spence and Woll, 1999; Lucas, 2001; Liddell, 2003). Sign language (SL) interpreting therefore aligns analytically, professionally, and pedagogically with other forms of interpreting, fitting the prototype formulated by Franz Pöchhacker: "Interpreting is a form of Translation in which a first and final rendition in another language is produced on the basis of a one-time presentation of an utterance in a source language" (2004: 11). In the case of SL interpreting, one of the languages is typically spoken, and one signed. SL interpreting is exceptional in requiring the transfer of meaning between language *modalities* (visual-gestural and oral-aural) as well as languages.

SL interpreting differs in several key ways, however, from those forms dominant within the early years of interpreting studies (where analysis often centered upon international gatherings, war crimes trials, and the like). Firstly, its norms correspond much more closely to those of community interpreting (CI) than to those of conference interpreting (Mikkelson, 1999). In particular, since SLs have occupied the position of 'minority languages' (in socioeconomic and geopolitical terms), issues of relative power and status – of the interpreters and of their clients, expressed through their languages – have been prominent in the theoretical development of the field. Furthermore, like CI, the work of SL interpreters is most commonly bilateral; however, the biological inaccessibility of spoken utterances to Deaf people presages a profession staffed almost exclusively by people whose dominant language is spoken. This has resulted in a highly imbalanced workforce wherein issues of cultural allegiance therefore become intense (Mindess, 1999). Secondly, the nature of the language pairs present in SL interpretations makes simultaneous, rather than consecutive, interpreting by far the more typical form, largely because the linguistic interference effects are minimized when the languages are produced and received through entirely different channels. The tacit expectation is therefore likely to be that SL interpreters will work in the simultaneous mode, despite the fact that they will be transferring meaning between modalities as well as languages – twice the task, to be done in a fraction of the time! Finally, it is necessary to distinguish between SL interpreting and transliteration: the latter term – particularly associated with the United States (Winston, 1989) – refers to the transfer of meaning from a spoken language to a manually coded form of the same language (e.g., English to Signed English). The linguistic status of these forms remains in dispute (Lucas, 2001), but either they are essentially English – in which case, no interpretation, in the sense defined here earlier, is taking place – or they fall within the range of 'natural' SL variation – in which case no exceptional descriptive apparatus is required to account for SL interpreting using such forms.

Historical Background

Historically, SL interpreting of some description has doubtless existed wherever communication has been mediated between signing and nonsigning people. The hearing children of Deaf, signing parents, becoming fluent bilinguals through natural language transmission, were most likely to act as interpreters (Preston, 1994). This task began to receive formal

recognition in the 1960s, with the first known attempt at institutionalization taking place in 1964 with the formation of the Registry of Interpreters for the Deaf in the United States (Frishberg, 1990). The need to carve out a distinct role for interpreters reflected anxiety about the conflation of interpreting with other relational positions, such as those of assistants or advocates, and with separable professions whose members had often undertaken to mediate communication – e.g., welfare officers, teachers, priests. The drive to formalize and tightly define the interpreter's role has been addressed in widespread debates over codes of ethics that recognize the interpreter's unique position of responsibility (Tate and Turner, 1997). In recent decades, SL interpreting has thus developed in many countries as an independent profession, regulated in order to institutionalize altruism, with increasingly structured and extensive education leading to professional status, and practitioner associations providing collective representation and strategic development (Stewart *et al.*, 1998).

Models and Paradigms

As SL interpreting emerged, the dominant paradigm inherited from the wider field inscribed a role representing the interpreter as a mere conduit through which messages could be transferred. Interpreters were understood and expected to have no more influence on meaning or on discourse dynamics than the handheld apparatus has on a cell phone conversation. In keeping with the paradigm, attempts to describe and explain the process of interpreting centered upon the desire to unpack the cognitive activity required, sometimes acknowledging the relevance of social context (Cokely, 1992).

In the late 1980s, however, an alternative perspective rose to prominence, inspired in particular by recognition that the 'conduit' model described a passive role for SL interpreters that was simply unrealistic. The natural lexical disparities between languages and the nonlinear, multilayered structure of naturally occurring dialogue required practitioners actively to reach decisions about how to convey meanings and maximize communicative equivalence (Roy, 2000a). In the United Kingdom, the switch to an 'interactional' model was signified by a small but momentous change in the SL interpreters' code of ethics: to the end of the statement "Interpreters shall interpret truly and faithfully and to the best of their ability between the parties without anything being added or omitted" were added the three significant little words "from the meaning." This paradigm shift also drew upon the steady growth in awareness of CI in general: as in the wider field (see Wadensjö, 1998), the normative image of the SL interpreter as an 'invisible' nonpresence within the prototypical interpreting triad has been superseded by accounts that explore the coparticipant status of the interpreter (Metzger, 1999; Harrington and Turner, 2001).

A key element in the development of understandings of the SL interpreter's role has been the attention paid to matters of power and control in discourse. Popular social misperceptions of Deaf people as intellectually incapable (for discussion, see Lane, 1992) have historically led to a paternalistic approach toward them. Since the profession began to grow independently, interpreters have been at pains to identify their impartiality. Nevertheless, a recurring train of thought (e.g., Baker-Shenk, 1991) has suggested that the interpreter's role as a communication broker also affords an opportunity to act as an 'ally,' engaging in the social repositioning of Deaf people by prioritizing Deaf participants' contributions and preferences. While such radical ideas do circulate, the strong but misguided normative expectation – that interpreters are communicatively neutral, do not change the course of dialogue, and make no self-generated contribution to interaction – remains largely in place, making the education of consumers a continuing priority (Marschark *et al.*, 2005).

Contexts and Developments

SL interpreting takes place across a full, growing range of social activity. Of particular significance to the deaf community is interpreting for deaf children during compulsory education (Seal, 2004): this is one community setting in which spoken language interpreting rarely occurs. The interpreter undertakes essentially the same process of transmitting meanings between pupils and teachers, although children are not expected to make firm teacher/interpreter role distinctions in this environment. Legal interpreting has also received greater attention in recent years (Turner and Kegl, 1995; Brennan and Brown, 2004), with researchers having uncovered particular translational dilemmas as regards the quality of evidence maintained in the transfer of meaning across modalities. While instances of interpreting in such settings are now relatively commonplace, there remain less-investigated areas, such as interpreting for Deafblind people (Peckford, 2000) and using 'international signing,' especially at multilingual conferences (e.g., Locker McKee and Napier, 2002).

Interpreter education increasingly follows the paths familiar in the broader field as SLs are steadily recognized by governments and formally taught up to higher educational levels. Innovative practices are required in order to deliver effective training

bilingually, integrating the contributions of Deaf and hearing educators (Roy, 2000b). In the early 21st century, new challenges face trainers, strategists, and policy makers (see Brien *et al.*, 2004). Among these is the growing presence of Deaf practitioners: their work often involves prepared texts or 'relay' interpreting (i.e., two practitioners conveying meaning via successive steps, each partially modifying the source message, between producer and receiver) and thus further problematizes familiar terms and definitions already questioned by analysts (e.g., Turner and Pollitt, 2002). Technological advances promise an expansion in remote interpreting, with digital video images obviating the need for face-to-face interaction. Early exploration of 'virtual signing,' using digitally created avatars, suggests the theoretical potential for the replacement, in the long term, of human mediation by technological resources: for the time being, human interpreters, often in unpredictable circumstances, perform this highly complex linguistic work.

Sign Language: Lexicography

G M Schermer, Dutch Sign Centre, Bunnik, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The modern concept of a dictionary as a table of words arranged alphabetically, including their pronunciation, spelling, and meaning, originated in the 17th century. The first dictionary, a table of alphabetically listed hard English words, was published in London in 1604.

In the next 100 years, dictionaries designed for all sorts of different groups became very popular. The first dictionary that was not specific to a particular group of readers came out in 1757 in two volumes by Samuel Johnson and colleagues: It was the first real dictionary of the English language. An interesting aspect of this dictionary was the way in which a lemma was defined: not in a neutral way, as we expect from modern dictionaries, but clearly reflecting the opinion of its makers. As it turned out, this feature would cause the philologist Richard Trench in 1855 to plead for a different type of dictionary – one that would incorporate every single word that existed in the entire English language, with every sense, meaning, alternate spelling, derivation, and etymology and, most importantly, a biography of every word to show how its meanings had changed over the centuries. To achieve this goal of creating a great dictionary, a network of volunteers was organized to provide the dictionary staff with the necessary written information and quotations of English words.

This brief history illustrates most of the questions and problems a lexicographer may come across in carrying out his or her work: What is the status of a dictionary, who is the potential user, what constitutes a lemma, who decides what should go into the dictionary and why, what are the limits of a lemma definition, what is the source of information, and who is a proper informant?

Although the first known 'dictionary' of signs was produced by John Bulwer in 1644, sign language lexicography did not really begin until 1965 when the first sign language dictionary based on linguistic principles was published (Stokoe *et al.,* 1965). This dictionary, DASL, has become the inspiration for sign language researchers.

In the next section, the most important aspects of sign language lexicography and the making of sign language dictionaries are discussed. There are two sets of issues: (1) those that relate to the process of making a dictionary and its organization: the type and function of the dictionary, data collection, informants, and the lexeme and its depiction, and (2) those that relate to the status of the language as a minority language: standardization, variants, and the dictionary as proof of a sign language being a full-fledged language.

Making a Dictionary and Its Organization

The history of most sign languages is one of oppression by hearing educationalists. Until the mid-1960s, most sign languages were not viewed as full-fledged languages, comparable to spoken languages. However, after that, once sign language research began to flourish in a country, usually the first major task was the compilation of a dictionary.

Type of Dictionary

The majority of published sign language dictionaries in book form are bilingual dictionaries: They usually offer translations of signs into the written language of the hearing community. Problems stem from the absence of orthographies for sign languages. Most sign language dictionaries produced in the 1970s and 1980s were unidirectional bilingual dictionaries (O'Rourke, 1978; Sternberg, 1981).The loose-leaved SLN (Netherlands Sign Language) children's dictionary (Schermer *et al.*, 1988) is an example of a simple bidirectional, bilingual dictionary: It can be organized according to hand shape or alphabetically. Examples of the most sophisticated bidirectional and bilingual dictionaries in book form are the Auslan dictionary (Johnston, 1989), the dictionary of British Sign Language (Brien, 1992), the dictionary of Italian Sign Language (Radutzky, 1992), and the Finnish Sign Language Dictionary (Malm, 1998). Examples of bidirectional, bilingual dictionaries on CD-ROM or on the Internet are Signs of Australia (Johnston, 1997),

The modern concept of a dictionary as a table of words arranged alphabetically, including their pronunciation, spelling, and meaning, originated in the 17th century. The first dictionary, a table of alphabetically listed hard English words, was published in London in 1604.

In the next 100 years, dictionaries designed for all sorts of different groups became very popular. The first dictionary that was not specific to a particular group of readers came out in 1757 in two volumes by Samuel Johnson and colleagues: It was the first real dictionary of the English language. An interesting aspect of this dictionary was the way in which a lemma was defined: not in a neutral way, as we expect from modern dictionaries, but clearly reflecting the opinion of its makers. As it turned out, this feature would cause the philologist Richard Trench in 1855 to plead for a different type of dictionary – one that would incorporate every single word that existed in the entire English language, with every sense, meaning, alternate spelling, derivation, and etymology and, most importantly, a biography of every word to show how its meanings had changed over the centuries. To achieve this goal of creating a great dictionary, a network of volunteers was organized to provide the dictionary staff with the necessary written information and quotations of English words.

This brief history illustrates most of the questions and problems a lexicographer may come across in carrying out his or her work: What is the status of a dictionary, who is the potential user, what constitutes a lemma, who decides what should go into the dictionary and why, what are the limits of a lemma definition, what is the source of information, and who is a proper informant?

Although the first known 'dictionary' of signs was produced by John Bulwer in 1644, sign language lexicography did not really begin until 1965 when the first sign language dictionary based on linguistic principles was published (Stokoe *et al.,* 1965). This dictionary, DASL, has become the inspiration for sign language researchers.

In the next section, the most important aspects of sign language lexicography and the making of sign language dictionaries are discussed. There are two sets of issues: (1) those that relate to the process of making a dictionary and its organization: the type and function of the dictionary, data collection, informants, and the lexeme and its depiction, and (2) those that relate to the status of the language as a minority language: standardization, variants, and the dictionary as proof of a sign language being a full-fledged language.

Making a Dictionary and Its Organization

The history of most sign languages is one of oppression by hearing educationalists. Until the mid-1960s, most sign languages were not viewed as full-fledged languages, comparable to spoken languages. However, after that, once sign language research began to flourish in a country, usually the first major task was the compilation of a dictionary.

Type of Dictionary

The majority of published sign language dictionaries in book form are bilingual dictionaries: They usually offer translations of signs into the written language of the hearing community. Problems stem from the absence of orthographies for sign languages. Most sign language dictionaries produced in the 1970s and 1980s were unidirectional bilingual dictionaries (O'Rourke, 1978; Sternberg, 1981).The loose-leaved SLN (Netherlands Sign Language) children's dictionary (Schermer *et al.*, 1988) is an example of a simple bidirectional, bilingual dictionary: It can be organized according to hand shape or alphabetically. Examples of the most sophisticated bidirectional and bilingual dictionaries in book form are the Auslan dictionary (Johnston, 1989), the dictionary of British Sign Language (Brien, 1992), the dictionary of Italian Sign Language (Radutzky, 1992), and the Finnish Sign Language Dictionary (Malm, 1998). Examples of bidirectional, bilingual dictionaries on CD-ROM or on the Internet are Signs of Australia (Johnston, 1997),

several CD-ROMs on SLN (Schermer *et al.*, 1996–2002), and the digital sign language dictionary on VGT (Flemish Sign Language; Van Herreweeghe *et al.,* 2004). These dictionaries represent the lexicon of a signed language by an ordered sequence of head signs, which they subsequently explain in the second language. This requires a detailed analysis of the features of phonology of signs.

Monolingual dictionaries, offering citation forms and definitions in the sign language itself, are virtually impossible to make in book form. Today, with the availability of CD-ROM technology and digitized video stored in computerized databases, it is possible to make a monolingual dictionary. A prototype of such a dictionary was produced by Brien, Brennan, and Collins in 1996: the BSL/English Dictionary of Deaf Community and Culture on CD-ROM. In this dictionary, the meanings of signs are given directly in BSL, as is grammatical information on the type of sign. A great advantage of CD-ROM applications over traditional sign dictionaries is that they provide the users with demonstrations of how the sign is produced and offer the possibility of searching the linguistic parameters of a sign.

Web technology will make it feasible in the near future to produce true monolingual sign language dictionaries. To do full justice to the richness of the lexicon of sign languages, it is necessary to develop and produce monolingual dictionaries. Bilingual dictionaries should be based on monolingual dictionary information to avoid translation difficulties between the sign language and the spoken language of a community.

Function of a Dictionary

Spoken language dictionaries evolved from listing only difficult words to archiving the entire lexicon of a language: The number of words in a dictionary is seen as an indication of the complexity and thus the status of a language.

Sign language dictionaries are usually made for two purposes: to describe the language of the Deaf community and to make the language accessible for (hearing) language learners. The majority of deaf children have hearing parents, who need to learn a completely new language and require course materials and dictionaries to accomplish that task. More and more, we find examples of thematic dictionaries or dictionaries for specific groups and subjects: parents, children, teachers, and second language learners.

Data Collection and Informants

Spoken language lexicographers have access to large digital corpora of texts, which permit easy searching and concordance extraction. In contrast, sign language lexicographers have to rely on information from sign language users. The importance of data collection has long been neglected in sign language lexicography. In the early dictionaries, the source of the information in the dictionary was often not specified. In extreme cases, the entire dictionary was based on the information of one informant, the editor.

However, it is now common practice for sign lexicographers to define a set of criteria that informants have to meet. Most importantly, informants must be deaf native sign language users, preferably with deaf parents, and they have to be well-respected members of the Deaf community; in some cases, hearing children of deaf parents whose first language is a sign language are involved in data collection. Sign language dictionaries that are based on the information of hearing sign language users only (teachers, priests, linguists) are often not accepted by the Deaf community.

In contrast to spoken language dictionaries, which only include existing words, sign language dictionaries often contain not only existing signs but also newly developed signs. For almost a century, the use of sign languages has been banned in education in Western Europe and North America. As a consequence, there are deficiencies in the sign language corpora compared to the spoken languages of the hearing community. The expansion of bilingual (sign language/ spoken language) programs and the continuing growth of educational interpreting at secondary and tertiary levels have created an urgent need for a coordinated effort to identify signs for technical terms and for school subjects. It is very important for native deaf signers to be involved in the development of new signs. One productive approach is to work with a team of native deaf signers, (deaf) linguists, and people who have specific content knowledge. Excellent examples of a series of dictionaries aimed at a specific profession for which new signs had to be developed are the sign language dictionaries produced by the Arbeitsgruppe Fachgebärden in Hamburg; for example, the one for Psychology.

The Lexeme and Its Depiction

Several issues must be considered in the debate over what constitutes a lemma. One issue is the productive versus the frozen (established) lexicon. Some lexicographers feel the need to incorporate both elements, since the frozen lexicon is such a small portion of the possible lexicon of most sign languages. Other lexicographers claim that their primary interest should be to define the lexical signs of a language. They make a distinction between a lexeme and a sign: Not all signs are lexemes but all lexemes are signs.

The grammatical information for a given lexeme poses difficulties for most sign language lexicographers: In most cases, there is no reference grammar for a sign language of the sort that would provide this type of information.

A feature specific to sign language dictionaries is the depiction of the signs: drawings, photographs, or, on CD-ROM or the Internet, a digital movie. The problem with drawings and photographs is that the movement and the nonmanual features of a sign cannot be depicted accurately. Digital movies are preferable. However, movies pose their own set of issues: determining what is the exact form of the citation (what should be done with optional nonmanual components, such as mouthings in some sign languages) and who can be a model (the model in a movie is often known to the deaf community and may be subject to criticism). To produce the most accurate movies, much research has been undertaken on background color, light, clothes of the model, signing speed, and the like.

Role of a Sign Language Dictionary, Standardization, and Variation

Role of a Sign Language Dictionary

Dictionaries clearly are much more than a text that describes the meaning of words. The word 'dictionary' suggests authority, status, and scholarship: The size of the dictionary, the paper that is used, and its cover all contribute to the status of the language described in it. The first dictionaries of sign languages not only served the purpose of describing the lexicon of the language; for most Deaf communities, they were also historic publications of paramount social importance that could be used as powerful instruments in the advancement of quality bilingual education, as well as in the full exercise of the constitutional rights of deaf people. Many introductions to sign dictionaries mention that their purpose is to elevate the status of the sign language, which may not have been considered a real language.

Standardization and Variation

Like spoken languages, sign languages exhibit variation at all levels in phonology, morphology, and syntax. Furthermore, studies have shown that, as in spoken languages, variation in sign languages correlates with social factors, such as region, age, gender, ethnicity, and socioeconomic status.

Sign language dictionaries deal with variation in the language in different ways. The majority of sign lexicographers attempt to produce a standardizing dictionary of the sign language or at least nominate one variant as the preferred one. Even if it is not the intention of a sign language lexicographer, the general public often interprets the information in the dictionary as *pre* scribed, rather than *des* cribed language. The fact that sign languages lack a written form confronts lexicographers with a problem of determining which form of the sign is the correct one and should therefore be the citation form in the dictionary. Lexicographers have to determine, one way or the other, whether an item in the language is used by the majority of a given population and can thus be labeled standard or whether it is a dialect form. Although the more sophisticated dictionaries account for variation in one way or the other, few dictionaries have been based on extensive research into language variation. The new web technology and computerized database technology may solve this problem in the near future, helping sign language lexicography come of age.

Sign Language: Morphology

T Johnston, Macquarie University, Sydney, Australia

© 2006 Elsevier Ltd. All rights reserved.

Morphology deals with the regular, minimal, meaning-bearing units in language – morphemes – which are words or parts of words. Morphemes can effect changes in meaning by signaling the creation of a new word or a change in word class (derivation), or by signaling grammatical information such as case, number, person, aspect, tense, etc., (inflection) (*see* **Morpheme**).

Individual signs in a signed language are the basic equivalent of words in a spoken language. Each signed language has a vocabulary of conventional lexical signs which are often monomorphemic. In the closely related Australian and British Sign Languages (Auslan and BSL, respectively), for example, none of the formational aspects of the sign SISTER has any separate meaning of its own (*see* **Sign Language: Phonology** and **Sign Languages of the World**). See **Figure 1**.

The type of morphological processes commonly found in signed languages seems to be influenced by the fact that most lexical signs are monosyllabic or, at most, bisyllabic (Johnson and Liddell, 1986; Liddell, 1984; Sandler, 1995; Wilbur, 1993). Signed languages appear to favor simultaneous sign internal modification, rather than the concatenation of morphemes. This may be related to the fact that the larger size of the articulators in signed languages (the hands, arms, face, and body) means that each sign gesture takes more time to execute than each spoken articulatory gesture (Bellugi and Fischer, 1972). If segments are added to a stem, producing a multisyllabic sign, processes of assimilation and deletion tend to restructure the resulting sign into a bisyllabic or monosyllabic one with simultaneously expressed morphemes.

This process is most clearly seen in the formation of new signs through compounding. In Auslan/BSL, for example, the sign CHECK derives from SEE and MAYBE. SEE has lost its outward movement with final hold and has incorporated the anticipated handshape of MAYBE, while MAYBE has lost its repeated twisting movement. The compound has a single syllable (Sutton-Spence and Woll, 1999). See **Figure 2.**

With the exception of prefixes in Israeli Sign Language (Aronoff *et al.*, 2000), the few affixes that have been identified in signed languages are all suffixes. Indeed, many appear to have grammaticized from one of the elements in erstwhile compounds. For example, a negative suffix –NEG can be attached to AGREE to derive the new sign DISAGREE, in Auslan/BSL. The affix appears to be a reduced form of an independent sign, which itself seems related to a gesture (meaning something like 'not know') shared with the hearing culture. A similar suffix (in both form and meaning) has been identified in a number of signed languages (Zeshan, forthcoming). See **Figure 3**.

Researchers have also identified a derivational process whereby stem signs for certain units that are enumerable (e.g., TOMORROW, WEEK) may incorporate

Morphology deals with the regular, minimal, meaning-bearing units in language – morphemes – which are words or parts of words. Morphemes can effect changes in meaning by signaling the creation of a new word or a change in word class (derivation), or by signaling grammatical information such as case, number, person, aspect, tense, etc., (inflection) (*see* **Morpheme**).

Individual signs in a signed language are the basic equivalent of words in a spoken language. Each signed language has a vocabulary of conventional lexical signs which are often monomorphemic. In the closely related Australian and British Sign Languages (Auslan and BSL, respectively), for example, none of the formational aspects of the sign SISTER has any separate meaning of its own (*see* **Sign Language: Phonology** and **Sign Languages of the World**). See Figure 1.

The type of morphological processes commonly found in signed languages seems to be influenced by the fact that most lexical signs are monosyllabic or, at most, bisyllabic (Johnson and Liddell, 1986; Liddell, 1984; Sandler, 1995; Wilbur, 1993). Signed languages appear to favor simultaneous sign internal modification, rather than the concatenation of morphemes. This may be related to the fact that the larger size of the articulators in signed languages (the hands, arms, face, and body) means that each sign gesture takes more time to execute than each spoken articulatory gesture (Bellugi and Fischer, 1972). If segments are added to a stem, producing a multisyllabic sign, processes of assimilation and deletion tend to restructure the resulting sign into a bisyllabic or monosyllabic one with simultaneously expressed morphemes.

This process is most clearly seen in the formation of new signs through compounding. In Auslan/BSL, for example, the sign CHECK derives from SEE and MAYBE. SEE has lost its outward movement with final hold and has incorporated the anticipated handshape of MAYBE, while MAYBE has lost its repeated twisting movement. The compound has a single syllable (Sutton-Spence and Woll, 1999). See Figure 2.

With the exception of prefixes in Israeli Sign Language (Aronoff *et al.*, 2000), the few affixes that have been identified in signed languages are all suffixes. Indeed, many appear to have grammaticized from one of the elements in erstwhile compounds. For example, a negative suffix –NEG can be attached to AGREE to derive the new sign DISAGREE, in Auslan/BSL. The affix appears to be a reduced form of an independent sign, which itself seems related to a gesture (meaning something like 'not know') shared with the hearing culture. A similar suffix (in both form and meaning) has been identified in a number of signed languages (Zeshan, forthcoming). See Figure 3.

Researchers have also identified a derivational process whereby stem signs for certain units that are enumerable (e.g., TOMORROW, WEEK) may incorporate

numeral handshapes to create specific signs for specific numbers of these units (e.g., IN TWO DAYS, TWO-WEEKS). See Figure 4.

Modification of the quality of the movement in a sign can also be used to derive new signs, such as BUSY from WORK (Auslan/BSL). A similar process derives NARROW-MINDED/PRUDISH from CHURCH in ASL, and this has been compared to templated morphology as found in Semitic languages (Fernald and Napoli, 2000). See Figure 5.

It is often difficult to clearly distinguish between stem modification or suprasegmental modification in signed languages. In many respects, modifying the movement parameter of a sign is akin to changing a vowel (a stem modification); however, in others, modifying for manner of movement is akin to tone (a suprasegmental modification). The derivation of nouns from verbs in some signed languages is a case in point.

Originally described in ASL (Supalla and Newport, 1978), this morphological process, in which nouns are derived from verbs by a sign-internal modification of movement, also has parallels in other signed languages. The continuous single movement found in the verb is modified to be restrained and tense, and often repeated, in the noun, as in the Auslan/BSL pair DOOR and OPEN-DOOR. See Figure 6.

However, typical exemplars in many signed languages overlap considerably in both form and meaning, and the productivity of the derivational process appears influenced by underlying iconicity. Though it is to be expected that derivational paradigms in any language will be restricted and morpheme productivity limited, for some signed languages at least the degree of grammaticization of these modifications is as yet uncertain.

Morphemes and morphological processes can also signal the inflection of existing signs, adding grammatical information (e.g., marking for number, person, aspect, etc.) while maintaining the essential lexical meaning of the stem. Inflections in signed and spoken languages can be found on nominals or predicates (verbs and adjectives).

Inflection by concatenative affixation appears to be extremely rare in signed languages. One example is a nominal genitive suffix in Auslan which is used to signal possessive relationships between two nouns. This sign is not used as a free morpheme of any kind, but only as a suffix, as in MOTHER+GEN SISTER+GEN HUSBAND to mean 'mother's sister's husband.'

Data from a growing number of signed languages have shown that all of them exploit space and movement patterns inherent in sign formation to convey information regularly encoded in the inflectional

Figure 7 Inflection ('person agreement') through movement modification in the Auslan/BSL sign GIVE, and the Auslan sign HELP. Reproduced from Johnston T & Schembri A (eds.) (2003). *The survival guide to Auslan: a beginner's pocket dictionary of Australian Sign Language*. Sydney: North Rocks Press with permission.

systems of spoken languages. Indeed, the markings often appear to be in part phonologically conditioned. For example, space will be exploited when a sign is not anchored throughout its production at a particular location on the body, or if its movement parameter is not specified for repetition.

These processes are exemplified in both nominal and verbal inflections. In nominal signs, inflection for plurality can be marked by repetition (often in different locations if the sign is not anchored). Spatial modifications can also signal topographical information about referents (e.g., a noun may be placed in the signing space to mean 'thing-at-such-and-such-a-place').

A basic tripartite division of ASL verb signs as plain, spatial, and agreeing (Padden, 1988) has been found to apply to signed languages to which the framework has been applied (with or without various modifications and reinterpretations).

For example, no sign language lacks the ability to modify the direction of the movement parameter of agreeing verbs so that the beginning and end points of these signs move between regions in the signing space associated with the *subject* (or the *agent*) and the *object* (or the *patient*) of the action. (Alternative interpretations of this phenomenon include those that assign *source* and *goal* as the underlying significance of these locations (Johnston, 1991; Meier, 1982).) The sign glossed as GIVE in many signed languages can have the meanings 'I give you' when moved from the signer to the interlocutor, or 'you give me' when moved from the interlocutor toward the signer, and 'he/she gives him/her' when moved between two (real or imaginary) third entities in the signing space. In spatial verbs the same mechanism is exploited to mark spatial and locative information. (Plain verbs are unable to exploit location and direction of movement in this way because they have a fixed place of articulation.) See Figure 7. For Padden and many linguists, the modifications on agreeing verbs are analyzed as non-concatenative affixes inflecting for person, while for other linguists the modifications indicate locations, depicting actions within a mental space representation of an event (Liddell, 2003).

Figure 8 Inflection ('distribution') through movement modification in Auslan/BSL. Reproduced from Johnston T & Schembri A (eds.) (2003). *The survival guide to Auslan: a beginner's pocket dictionary of Australian Sign Language*. Sydney: North Rocks Press with permission.

A second related phenomenon in verb inflection refers to distribution and involves a 'plural sweep' in which the end point is moved in an arc through locations associated with referents or relocated and redirected at each in a series of repetitions, as in the modification of ASK to mean 'ask all' or 'ask each.' See Figure 8.

Similarly, modifications can be made to the movement parameter of verb signs to express a number of aspectual nuances. Researchers in many signed languages have identified similar patterns of movement modification, with similar meanings, as first described in ASL (Klima *et al.*, 1979). For example, similar patterns of cyclic and repeated movements also convey durational and continuative aspect (e.g., 'ask repeatedly'). Aspectual and distributional modifications can also combine to create a morphologically complex multilayered pattern of modifications (e.g., 'ask all repeatedly').

Verbal modifications based on suprasegmental modifications involve nonmanual features such as facial expression. A large number of facial expressions have been identified across many signed languages. Two found in Auslan/BSL – 'th' (as if producing an interdental fricative) and 'mm' (a bilabial protrusion) – are examples also found in some

other signed languages. The former implies lack of control or inattention, the latter implies relaxed normality and when co-articulated with DRIVE they mean 'drive carelessly' and 'drive relaxed and normally', respectively.

As with the derivation of nominals, the extent of the grammaticization of movement modifications inflecting for aspect and manner, and their obligatoriness, within many signed languages, is still yet to be determined, or, at minimum, appears to vary.

Though many signs are monomorphemic or bimorphemic, highly iconic lexical signs, of which there are significant numbers in any signed language, often have more than two identifiable morphemes – they are multimorphemic. Take the highly iconic sign DRINK/CUP (as if holding a cup to one's mouth) which is found in many signed languages with a similar form and meaning. It consists of at least three morphemes: The handshape signifies holding a cup, the movement signifies turning a cup toward the mouth, and the location signifies the mouth.

Importantly, there are a significant number of signs produced in many utterances in any signed language which are neither lexical nor grammatical signs. They display a moderate to high degree of conventionality in the form and meaning of handshapes, while movements and locations appear to be draw on particular representational exigencies of the moment. These signs are variously called classifier signs or polymorphemic signs.

Polymorphemic signs are used to convey a large amount of visual spatial information about participants in a situation (e.g., the size and shape and location of entities, how they may be handled, their position in space, and their path and manner of movement). In the following sign, the upright index finger represents a person, the palm the front of the body, the movement left to right the path, and the bobbing up and down movement a walking action. See Figure 9.

PERSON-WALK-BY-FROM-RIGHT-TO-LEFT

Figure 9 A complex polymorphemic sign found in many signed languages. Reproduced from Johnston T & Schembri A (eds.) (2003). *The survival guide to Auslan: a beginner's pocket dictionary of Australian Sign Language*. Sydney: North Rocks Press with permission.

No signed language appears to lack these types of signs, and a considerable literature has been generated in an attempt to analyze them systematically in linguistic terms (Emmorey, 2003; Engberg-Pedersen, 1993; McDonald, 1982; Schick, 1990; Supalla, 1986). They can create monosyllabic polymorphemic signs which are unattested in spoken languages and which resist analysis into roots and listable morphemes. They remain a problem area for linguists (Schembri, 2003).

Original research into signed languages aimed to establish them as real languages with language-like characteristics. Subsequent research has aimed to establish the validity of linguistic universals that had been made on the basis of the study of spoken languages only, or to determine the impact of modality on language structure (e.g., Meier *et al.*, 2002).

Another line of research seeks to acknowledge the degree to which signed languages are different from spoken languages. Depending on how the dynamics of spoken language are understood, these differences have been perceived as additional special characteristics peculiar to language in the visual-gestural modality, or as differences of degree only which have been occasioned by modality, e.g., some representational resources, such as space, are universally exploited in signed languages. For some linguists, the exploitation of a spatial and iconic morphology is seen as unique to signed languages but is nonetheless analyzed as part of a fully linguistic system of agreement (Aronoff *et al.*, 2000), for others it represents a fusion of elements of language and gesture (Liddell, 2003). For yet others, these face-to-face representational resources are recognized as available to *all* language users – even if they are underexploited in spoken languages and are ignored in most grammars. They saturate the lexico-grammar of signed languages because they are always available in languages that are embodied and, of necessity, always in view (Johnston, 1992).

It is as yet unclear if all of the phenomena of sign language morphology can be properly dealt with as 'linguistic,' narrowly defined. Insofar as it may contribute to the redefinition of what is 'language' or what is properly 'linguistic,' the short history of the study of signed languages belies its relative importance to linguistics.

Sign Language: Overview

W Sandler, University of Haifa, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

In many ways, sign languages are like spoken languages: They are natural languages that arise spontaneously wherever there is a community of communicators; they effectively fulfill all the social and mental functions of spoken languages; and they are acquired without instruction by children, given normal exposure and interaction. These characteristics have led many linguists to expect sign languages to be similar to spoken languages in significant ways. However, sign languages are different too: As manual–visual languages, sign languages exploit a completely different physical medium from the vocal–auditory system of spoken languages. These two dramatically different physical modalities are also likely to have an effect on the structure of the languages through which they are transmitted.

It is of special interest, then, to compare natural languages in the two modalities. Where the two systems converge, universal linguistic properties are revealed. Where they diverge, the physical medium of transmission is implicated, and its contribution to the form of language in both modalities is illuminated. Neither can be seen quite so clearly if linguists restrict their study to spoken language alone (or to sign language alone). For this and other related reasons, it is often remarked that sign languages provide

us with a natural laboratory for studying the basic characteristics of all human language.

Once the existence of natural language in a second modality is acknowledged, questions such as the following arise: How are such languages born? Are the central linguistic properties of sign languages parallel to those of spoken languages? Is sign language acquired by children in the same stages and time frame as spoken language? Are the same areas of the brain responsible for language in both modalities? What role does modality play in structuring language? In other words, within the architecture of human cognition, do we find the structure of one language 'faculty' or two? Although there is no conclusive answer to this deceptively simple question, an impressive body of research has greatly expanded our understanding of the issues underlying it.

How Do Sign Languages 'Happen'?

Evolution made language possible scores of millennia ago, and there is no human community without it. What sign language teaches us is that humans have a natural propensity for language in two different modalities: vocal–auditory and manual–visual. Since the human ability to use language is so old, and since speech is the predominant medium for its transmission, it seems that spoken languages are either also very old or descended from other languages with a long history. However, sign languages do not have the same histories as spoken languages because special conditions are required for them to arise and persevere, and for this reason they can offer unique insight into essential features of human language.

The first lesson sign language teaches us is that, given a community of humans, language inevitably emerges. Although we have no direct evidence of the emergence of any spoken language, we can get much closer to the origin of a sign language and, in rare instances, even watch it come into being.

Wherever deaf people have an opportunity to gather and interact regularly, a sign language is born. Typically, deaf people make up a very small percentage of the population (approximately 0.23% in the United States, according to the National Center for Health Statistics, 1994) so that in any given local social group, there may be no deaf people at all or very few of them. The most common setting in which a deaf community can form, then, is a school for deaf children. Such schools only began to be established approximately 200 years ago in Europe and North America. On the basis of this historical information and some reported earlier observations of groups of people using sign language, it is assumed that the oldest extant sign languages do not date back farther than approximately 300 years (Woll *et al.*, 2001). Currently, linguists have the rare opportunity to observe the emergence and development of a sign language from the beginning in a school established in Nicaragua only approximately 25 years ago – an opportunity that is yielding very interesting results.

Graduates of such schools sometimes choose to concentrate in certain urban areas, and wider communities arise and grow, creating their own social networks, institutions, and art forms, such as visual poetry (Padden and Humphries, 2005; Sandler and Lillo-Martin, 2005; Sutton-Spence and Woll, 1999). Deaf society is highly developed in some places, and the term 'Deaf' with a capital D has come to refer to members of a minority community with its own language and culture rather than to people with an auditory deficit.

It is not only the genesis of a sign language that is special; the way in which it is passed down from generation to generation is unusual as well. Typically, fewer than 10% of deaf children acquire sign language from deaf parents, and of those deaf parents, only a small percentage are native signers. The other 90+% of deaf children have hearing parents and may only be exposed to a full sign language model when they go to school. These social conditions taken together with certain structural properties of sign languages have prompted some linguists to compare them to spoken creoles (Fischer, 1978).

Another way in which a deaf social group and concomitant sign language can form is through the propagation of a genetic trait within a small village or town through consanguineous marriage, resulting in a proportionately high incidence of deafness and the spread of the sign language among both deaf and hearing people. Potentially, this kind of situation can allow us to observe the genesis and development of a language in a natural community setting. Although the existence of such communities has been reported occasionally (see Groce, 1985), no comprehensive linguistic description of a language arising in such a community has been provided.

These, then, are the ways in which sign languages happen. The existence of many sign languages throughout the world – the number 103 found in the Ethnologue database is probably an underestimate – confirms the claim that the emergence of a highly structured communication system among humans is inevitable. If the oral–aural channel is unavailable, language springs forth in the manual–visual modality.

Not only does such a system emerge in the absence of audition, but its kernels can be also observed even in the absence of both a community and a language model. Deaf children who live in hearing households in which only oral language is used, who have not yet

experienced speech training, and thus have no accessible language model, devise their own systematic means of communication called home sign, studied in exquisite detail by Goldin-Meadow and colleagues (Goldin-Meadow, 2003). The gesture talk of these children contains the unmistakable imprint of a real linguistic system, and as such it offers a unique display of the fundamental human genius for language.

At the same time, the form and content of home sign are rudimentary and do not approach the richness and complexity of a language used by a community, spoken or signed. This confronts us with another important piece of information: Language as we know it is a social phenomenon. Although each brain possesses the potential for language, it takes more than one brain to create a complex linguistic system.

The Linguistic Structure of Sign Language

Hearing people use gesture, pantomime, and facial expression to augment spoken language. Naturally, the ingredients of these forms of expression are available to sign languages too. The apparent familiarity of the raw material that contributes to the formation of sign languages has led many a naïve observer to the mistaken assumption that sign languages are actually simple gesture systems. However, instead of forming an idiosyncratic, ancillary system like the one that accompanies speech, these basic ingredients contribute to a primary linguistic system in the creation of a sign language, a system with many of the same properties found in spoken languages. In fact, linguistic research has demonstrated that there are universal organizing principles that transcend the physical modality, subsuming spoken and signed languages alike.

The Phonology of Sign Language

William Stokoe (1960) demonstrated that the signs of American Sign Language (ASL) are not gestures: They are not holistic icons. Instead, Stokoe showed that they are composed of a finite list of contrastive meaningless units like the phonemes of spoken languages. These units combine in constrained ways to create the words of the language. Although there are some differences among different sign languages in their phonological inventories and constraints, there are many common properties, and the generalizations presented here hold across sign languages, unless otherwise indicated.

Stokoe established three major phonological categories: hand shape, location, and movement. Each specification within each of the three major categories was treated as a phoneme in Stokoe's work. Later researchers accepted these categories but proposed that the specifications within each category function

Figure 1 ASL minimal pair distinguished by a location feature. (A) SICK and (B) TOUCH.

not as phonemes but as phonological features. The ASL signs SICK and TOUCH, illustrated in Figure 1, have the same hand shape and the same straight movement. They are distinguished by location only: The location for SICK is the head, whereas the location for TOUCH is the nondominant hand. Minimal pairs such as this one, created by differences in one feature only, exist for the features of hand shape and movement as well. Although the origins of these and other (but certainly not all) signs may have been holistic gestures, they have evolved into words in which each formational element is contrastive but meaningless in itself.

Two other defining properties of phonological systems exist in sign languages as well: constraints on the combination of phonological elements and rules that systematically alter their form. One phonological constraint on the form of a (monomorphemic) sign concerns the set of two-handed signs. If both hands are involved, and if both hands also move in producing the sign (unlike TOUCH, in which only one hand moves), then the two hands must have the same hand shape and the same (or mirror) location and movement (Battison, 1978). An example is DROP, shown in Figure 2B: Both hands move, and they are identical in all other respects as well. The second defining property, changes in the underlying phonological form of a sign, is exemplified by hand shape assimilation in compounds. In one lexicalized version of the ASL compound, MIND + DROP = FAINT, the hand shape of the first member, MIND, undergoes total assimilation to the hand shape of the second member, DROP, as shown in Figure 2.

Stokoe believed that hand shapes, locations, and movements cooccur simultaneously in signs, an internal organization that differs from the sequentiality of consonants and vowels in spoken language. Liddell (1984) took exception to that view, showing that there is phonologically significant sequentiality in this structure. Sandler (1989) further refined that position, arguing that the locations (L) and movement (M)

Figure 2 Hand configuration assimilation in the ASL compound. (A) MIND + (B) DROP = (C) FAINT.

Figure 3 The canonical form of a sign. From Sandler (1989).

within a sign are sequentially ordered, whereas the hand configuration (HC) is autosegmentally associated to these elements – typically, one hand configuration (i.e., one hand shape with its orientation) to a sign, as shown in the representation in Figure 3. The first location of the sign TOUCH in Figure 1B, for example, is a short distance above the nondominant hand, the movement is a straight path, and the second location is in contact with the nondominant hand. The hand shape of the whole sign is .

Under assimilation, as in Figure 2, the HC of the second member of the compound spreads regressively to the first member in a way that is temporally autonomous with respect to the Ls and Ms, manifesting the autosegmental property of stability (Goldsmith, 1979). The sequential structure of signs is still a good deal more limited than that of words in most spoken languages, however, usually conforming to this canonical LML form even when the signs are morphologically complex (Sandler, 1993).

Morphology

All established sign languages studied to date, like the overwhelming majority of spoken languages, have complex morphology. First, as shown in Figure 2, compounding is very common. In addition, some sign languages have a limited number of sequential affixes. For example, Israeli Sign Language (ISL) has a derivational negative suffix, similar in meaning to English *-less*, that was grammaticalized from a free word glossed NOT-EXIST. This suffix has two allomorphs, depending on the phonological form of the base, illustrated in Figure 4. If the base is two-handed, so is the suffix, whereas one-handed bases trigger the one-handed allomorph of the suffix.

Sign languages typically have a good deal of complex morphology, but most of it is not sequential like the examples in Figures 3 and 4. Instead, signs gain morphological complexity by simultaneously incorporating morphological elements (Fischer and Gough, 1978). The prototypical example, first described in detail in ASL (Padden, 1988) but apparently found in all established sign languages, is verb agreement. This inflectional system is prototypical not only because of the simultaneity of structure involved but also because of its use of space as a grammatical organizing property.

The system relies on the establishment of referential loci – points on the body or in space that refer to referents in a discourse – that might be thought of as the scaffolding of the system. In Figure 5, loci for first person and third person are established.

In the class of verbs that undergoes agreement, the agreement markers correspond to referential loci established in the discourse. Through movement of the hand from one locus to the other, the subject is marked on the first location of the verb and the object on the second. Figure 6A shows agreement for the ASL agreeing verb, ASK, where the subject is first person and the object is third person. Figure 6B shows the opposite: third person subject and first person object. The requirement that verb agreement must refer independently to the first and last locations in a sign was one of the motivations for Liddell's (1984) claim that signs have sequential structure.

Although each verb in Figure 6 includes three morphemes, each still conforms to the canonical LML form shown in Figure 3. The agreement markers are encoded without sequential affixation. Sign language verb agreement is a linguistic system, crucially entailing such grammatical concepts as coreference, subject and object, and singular and plural. It is also characterized by sign language-specific properties, such as the restriction of agreement to a particular class of verbs (Padden, 1988), identified mainly on semantic grounds (Meir, 2002).

Figure 5 Referential loci. (A) First person. (B) Third person.

Figure 6 Verb agreement. (A) 'I ask him/her.' (B) 's/he asks me.'

Another productive inflectional morphological system found across sign languages is temporal and other aspectual marking, in which the duration of Ls and Ms, the shape of the movement path, or both may be altered, and the whole form may be reduplicated, to produce a range of aspects, such as durational, continuative, and iterative (Klima and Bellugi, 1979). This system has templatic characteristics, lending itself to an analysis that assumes CV-like LM templates and nonlinear associations of the kind McCarthy (1981) proposed for Semitic languages (Sandler, 1989, 1990).

Figure 4 demonstrated that some limited sequential affixation exists in sign languages. However, the most common form of sign language words by far, whether simple or complex, is LML (setting aside gemination of Ls and Ms in the aspectual system, which adds duration but not segmental content). In fact, even lexicalized compounds such as the one shown in Figure 2 often reduce to this LML form. If movement (M) corresponds to a syllable nucleus in sign language, as Perlmutter (1992), Brentari (1998), and others have argued, then it appears that monosyllabicity is ubiquitous in ASL (Coulter, 1982) and in other sign languages as well. In the midst of a morphological system with many familiar linguistic characteristics (e.g., compounding, derivational morphology, inflectional morphology, and allomorphy), we see in the specific preferred monosyllabic form of sign language words a clear modality effect (Sandler and Lillo-Martin, 2005).

No overview of sign language morphology would be complete without a description of the classifier subsystem. This subsystem is quintessentially 'sign language,' exploiting the expressive potential of two hands forming shapes and moving in space, and molding it into a linguistic system (Emmorey, 2003; Supalla, 1986). Sign languages use classifier constructions to combine physical properties of referents with the spatial relations among them and the shape and manner of movement they execute. In this subsystem, there is a set of hand shapes that classify referents in terms of their size and shape, semantic properties, or other characteristics in a classificatory system that is reminiscent of verbal classifiers found in a variety of spoken languages (Senft, 2002). These hand shapes are the classifiers that give the system its name. An example of a classifier construction is shown in Figure 7. It describes a situation in which a person is moving ahead, pulling a recalcitrant dog zigzagging behind. The hand shape embodies an upright human classifier and the hand shape a legged creature.

What is unusual about this subsystem is that each formational element – the hand shape, the location, and the movement – has meaning. That is, each has morphological status. This makes the morphemes of classifier constructions somewhat anomalous since sign language lexicons are otherwise built of morphemes and words in which each of these elements is meaningless and has purely phonological status. Furthermore, constraints on the cooccurrence of these elements in other lexical forms do not hold on

Figure 7 Classifier construction in ASL.

classifier constructions. In Figure 7, for example, the constraint on interaction of the two hands described in the section on phonology is violated. Zwitserlood (2003) suggested that each hand in such classifier constructions is articulating a separate verbal constituent, and that the two occur simultaneously – a natural kind of structure in sign language and found universally in them, but one that is inconceivable in spoken language. Once again, sign language presents a conventionalized system with linguistic properties, some familiar from spoken languages and some modality driven.

Syntax

As in other domains of linguistic investigation, the syntax of sign languages displays a large number of characteristics found universally in spoken languages. A key example is recursion – the potential to repeatedly apply the same rule to create sentences of ever increasing complexity – argued to be the quintessential linguistic property setting human language apart from all other animal communication systems (Hausser *et al.*, 2002). Specifically, through embedding or conjoining, recursion can result in sentences of potentially infinite length. These two different ways of creating complex sentences have been described and distinguished from one another in ASL. For example, a process that tags a pronoun that is coreferential with the subject of a clause onto the end of a sentence may copy the first subject in a string, only if the string contains an embedded clause, but not if the second clause is coordinate (Padden, 1988). In example (1), the subscripts stand for person indices marked through verb agreement, and INDEX is a pointing pronominal form, here a pronoun copy of the matrix subject, MOTHER. (These grammatical devices were illustrated in Figures 5 and 6.)

(1a) MOTHER SINCE $_{i}$PERSUADE$_{j}$ SISTER $_{j}$COME$_{i}$ $_{i}$INDEX
'My mother has been urging my sister to come and stay here, she (mother) has.'

(1b) * $_{i}$HIT$_{j}$ $_{j}$INDEX TATTLE MOTHER $_{i}$INDEX.
'I hit him and he told his mother, I did.'

The existence of strict constraints on the relations among nonadjacent elements and their interpretation is a defining characteristic of syntax. A different category of constraints of this general type concerns movement of constituents from their base-generated position, such as the island constraints first put forward by Ross (1967) and later subsumed by more general constraints. One of these is the WH island constraint, prohibiting the movement of an element out of a clause with an embedded WH question. The sentence, *Lynn wonders [what Jan thinks]* is okay, but the sentence **It's Jan that Lynn wonders [what __ thinks]* is ruled out. Lillo-Martin (1991) demonstrated that ASL obeys the WH island constraint with the sentences shown in example (2). Given the relative freedom of word order often observed in sign languages such as ASL, it is significant that this variability is nevertheless restricted by universal syntactic constraints.

(2a) PRO DON'T-KNOW ['WHAT' MOTHER LIKE].
'I don't know what Mom likes.'
_____t

(2b) MOTHER, PRO DON'T KNOW ['WHAT' ____ LIKE].
* 'As for Mom, I don't know what likes.'

The line over the word MOTHER in (2b) indicates a marker that is not formed with the hands, in this case a backward tilt of the head together with raised eyebrows, marking the constituent as a topic (t) in ASL. There are many such markers in sign languages, which draw from the universal pool of idiosyncratic facial expressions and body postures available to all human communicators. These expressions and postures become organized into a grammatical system in sign languages.

A Grammar of the Face

When language is not restricted to manipulations of the vocal tract and to auditory perception, it is free to recruit any parts of the body capable of rapid, variegated articulations that can be readily perceived and processed visually, and so it does. All established sign languages that have been investigated use nonmanual signals – facial expressions and head and body postures – grammatically. These expressions are fully conventionalized and their distribution is systematic.

Early research on ASL showed that certain facial articulations, typically of the mouth and lower face, function as adjectivals and as manner adverbials, the latter expressing such meanings as 'with relaxation and enjoyment' and 'carelessly' (Liddell, 1980).

Figure 8 Lower face articulations. (A) ASL 'with relaxation and enjoyment.' (B) ISL 'carefully.' (C) BSL 'exact.'

Figure 9 Upper face articulations. (A) yes/no question, (B) WH question, and (C) 'shared information.'

Other sign languages have been reported to use lower face articulations in similar ways. The specific facial expressions and their associated meanings vary from sign language to sign language. Figure 8 gives examples of facial expressions of this type in ASL, ISL, and British Sign Language.

A different class of facial articulations, particularly of the upper face and head, predictably cooccur with specific constructions, such as yes/no questions, WH questions, and relative clauses in ASL and in many other sign languages. Examples from ISL shown in Figure 9A illustrate a yes/no question (raised brows, wide eyes, and head forward), Figure 9B a WH question (furrowed brows and head forward), and Figure 9C the facial expression systematically associated in that language with information designated as 'shared' for the purpose of the discourse (squinted eyes). Although some of these facial articulations may be common across sign languages (especially those accompanying yes/no and WH questions), these expressions are not iconic. Some researchers have proposed that they evolved from more general affective facial expressions associated with emotions. In sign languages, however, they are grammaticalized and formally distinguishable from the affective kind that signers, of course, also use (Reilly *et al.*, 1990).

Observing that nonmanual signals of the latter category often cooccur with specific syntactic constructions, Liddell (1980) attributed to them an expressly syntactic status in the grammar of ASL, a view that other researchers have adopted and expanded (Neidle *et al.*, 2000; Petronio and Lillo-Martin, 1997). A competing view proposes that they correspond to intonational tunes (Reilly *et al.*, 1990) and participate in a prosodic system (Nespor and Sandler, 1999). Wilbur (2000) presented evidence that nonmanuals convey many different kinds of information – prosodic, syntactic, and semantic. A detailed discussion can be found in Sandler and Lillo-Martin (2005).

Acquisition of Sign Language

Nowhere is the 'natural laboratory' metaphor more appropriate than in the field of sign language acquisition. This area of inquiry offers a novel and especially revealing vantage point from which to address weighty questions about the human capacity for language. Research has shown, for example, that children acquire sign language without instruction, just as hearing children acquire spoken language, and according to the same timetable (Newport and Meier, 1985). These findings lend more credence to the view, established by linguistic research on the adult system, that languages in the two modalities share a significant amount of cognitive territory; children come equipped for the task of acquiring language in either modality equally.

Studies have also shown that signing children attend to grammatical properties, decomposing and overgeneralizing them as they advance through the system, sometimes even at the expense of the iconic properties inherent in that system. For example, even the pointing gesture used for pronouns (see Figure 5) is analyzed as an arbitrary grammatical element by small children, who may go through a stage in which they make mistakes, pointing at 'you' to mean 'me' (Pettito, 1987). Meier (1991) discovered counter-iconic errors in verb agreement (see Figure 6), similarly indicating that children are performing a linguistic analysis, exploring spatial loci as grammatical elements and not as gestural analogues to actual behavior and events.

Due to the social conditions surrounding its acquisition, sign language lends novel insight into two key theories about language and its acquisition: the critical period hypothesis and the notion that the child makes an important contribution to the crystallization of a grammar. Some deaf children are raised in oral environments, gaining access to sign language later in life. Studies comparing the ASL performance of early and late learners found that the age of exposure is critical for acquisition of the full grammatical system (Newport, 1990) and its processing (Mayberry and Eichen, 1991), providing convincing support for Lenneberg's (1967) critical period hypothesis. An untainted perspective on the child's contribution can be gained where the input to the child is simpler and/or less systematic than a full language system, as with pidgins (Bickerton, 1981). Researchers

of the sign language that originated in the Nicaraguan school mentioned previously studied the communication system conventionalized from the home sign brought to the school by the first cohort of children. This system served as input to the second cohort of children younger than the age of 10 years who later arrived at the school. Comparing the language of the two cohorts, the researchers found that children make an important contribution: The second cohort of signers developed a significantly more structured and regular system than the one that served as their input (Kegl *et al.*, 1999; Senghas *et al.*, 2004).

Sign Language and the Brain

Broadly speaking, it is established that most spoken language functions involve extensive activity in specific areas of the left hemisphere of the brain, whereas much of visuospatial cognition involves areas of the right cerebral hemisphere. Therefore, the discovery that sign language, like spoken language, is primarily controlled by the left hemisphere despite its exploitation of the visuospatial domain is striking and significant (Emmorey, 2002; Poizner *et al.*, 1987). Various explanations for left hemisphere dominance for language are currently on the table, such as the more general ability of the left hemisphere to process rapidly changing temporal events (Fitch *et al.*, 1997). This explanation has been rejected for sign language by some researchers on the grounds that sign language production is slower than that of spoken language (Hickock *et al.*, 1996). Whatever explanation is ultimately accepted, Emmorey (2002) and others have argued that similarities in the kind of cognitive operations inherent in the organization and use of language in the two modalities should not be ignored in the search.

Although most language functions are controlled by the left hemisphere, some do show right hemisphere involvement or advantage. With respect to sign language, there is evidence that the right hemisphere may be more involved in producing and comprehending certain topographic/spatial aspects of sign language, particularly those involving classifier constructions (Emmorey *et al.*, 2002). Although this result sits well with the known right hemisphere advantage for spatial processing, it is made even more interesting when added to discoveries of right hemisphere dominance for certain other spoken and sign language functions that may be related to the classifier system, such as processing words with imageable, concrete referents (Day, 1979; Emmorey and Corina, 1993). Findings such as these are an indication of the way in which sign language research adds important pieces to the puzzle of language organization in the brain.

Language Modality, Language Age, and the Dinner Conversation Paradox

A large body of research, briefly summarized here, attributes to sign languages, essential linguistic properties that are found in spoken languages as well (Sandler and Lillo-Martin, 2005). Also, like different spoken languages, sign languages are not mutually intelligible. A signer of ISL observing a conversation between two signers of ASL will not understand it. Although cross sign language research is in its infancy, some specific linguistic differences from sign language to sign language have already been described.

At the same time, there is a rather large group of predictable similarities across sign languages and, as Newport and Supalla (2000: 109) stated, "A long dinner among Deaf users of different sign languages will, after a while, permit surprisingly complex interchanges." Here we find a difference between signed and spoken languages: One would hardly expect even the longest of dinners to result in complex interchanges among monolingual speakers of English and Mandarin Chinese. Although it is clear that more differences across sign languages will be uncovered with more investigation and more sophisticated research paradigms, it is equally certain that the dinner conversation paradox will persist. Two reasons have been suggested for crosssign language similarities: the effect of modality on language structure and the youth of sign languages.

Modality Effects

Modality is responsible for two interwoven aspects of sign language form, both of which may contribute to similarities across sign languages: (i) an iconic relation between form and meaning, and (ii) simultaneity of structure. Because the hands can represent physical properties of concrete objects and events iconically, this capability is abundantly exploited in sign languages, both in lexical items and in grammatical form. Although spoken languages exhibit some iconicity in onomatopoeia, ideophones, and the like, the vocal–auditory medium does not lend itself to direct correspondence between form and meaning so that the correspondence in spoken language is necessarily more arbitrary.

Iconicity in Sign Language Leafing through a sign language dictionary, one immediately notices the apparent iconicity of many signs. An example is the ISL sign for BOOK, shown in Figure 10, which has the appearance of a book opening. Although clearly

Figure 10 An iconic sign: (ISL) BOOK.

widespread, iconicity in sign language must be understood in the right perspective. Many signs are not iconic or not obviously motivated, among them the signs for abstract concepts that exist in all sign languages. Interestingly, even the iconicity of signs that are motivated is not nearly so apparent to nonsigners if the translations are not available (Klima and Bellugi, 1979). In addition, the presence of iconicity in sign language does not mean that their vocabularies are overwhelmingly similar to one another. In fact, although even unrelated sign languages have some overlap in vocabulary due to motivatedness, their vocabularies are much more different from one another than one might expect (Currie *et al.*, 2002). Nevertheless, the kind of symbolization and metaphoric extension involved in creating motivated signs may be universal (Taub, 2001). For example, a bird is represented in ISL with a sign that looks like wings and in ASL with a sign that looks like a beak, and experience with this kind of symbolization in either sign language may make such signs easier to interpret in the other.

Simultaneity in Sign Languages Another modality feature is simultaneity of structure, alluded to previously. Some researchers have argued that constraints on production, perception, and short-term memory conspire to create simultaneity of linguistic structure (Bellugi and Fischer, 1972; Emmorey, 2002). Interestingly, iconicity also makes a contribution to simultaneity of structure, especially when one looks beyond the lexicon to grammatical forms of a more complex nature.

The hands moving in space are capable of representing events that simultaneously involve a predicate and its arguments (e.g., giving something to someone or skimming across a bumpy surface in a car) with a form that is correspondingly simultaneous. The result is verb agreement (exemplified in Figure 6) and classifier constructions (exemplified in Figure 7). Therefore, these structures, with particular grammatical properties, are found in all established sign languages that have been studied, leading to the observation that sign languages belong to a single morphological type (Aronoff *et al.*, 2005). Although the grammatical details of this morphology differ from sign language to sign language, the principles on which they are based are the same, and this similarity makes another welcome contribution at the dinner table.

The Role of Language Age

Recent work pinpoints the role of language age in the structure of sign language, indicating how age may be partly responsible for the impression that crosssign language differences are less abundant than is the case across spoken languages. It does so by comparing the type of morphology ubiquitously present in sign languages with a language-specific type (Aronoff *et al.*, 2005). This study noted that the form taken by the verb agreement and classifier systems in all established sign languages is similar (although not identical) due to the modality pressures of iconicity and simultaneity sketched previously, but that sequential affixes of the kind exemplified in Figure 4 vary widely between the sign languages studied. Such affixes, arbitrary rather than iconic in form and limited in number, develop through grammaticalization processes, and these processes take time. Given time, more such arbitrary, sign language-specific processes are predicted to develop.

The physical channel of transmission affects language in both modalities. Where sign languages are more simultaneously structured, spoken languages are more linear. Where spoken languages are mostly arbitrary, sign languages have a good deal of iconicity. However, none of these qualities are exclusive to one modality; it is only a matter of degree.

Sign Language: Phonology

D Brentari, Purdue University, West Lafayette, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

It is taken as given that phonology refers to a level of that grammar that combines a finite number of meaningless features into an infinite number of pronounceable utterances and that the communication modality in which this phonology is expressed can be either auditory/vocal (i.e., a spoken language) or visual/gestural (a sign language). An important, but distinct, subject of investigation is whether phonology refers to the auditory signals and gestures of the vocal apparatus in a spoken language or the visual signals and gestures of the hands and body in a signed language with the phonological grammar. With this in mind, two of the primary theoretical goals of studying the phonology of sign languages are to put into sharp contrast those aspects of phonology that are shared by all languages, both signed and spoken – and thereby be able more clearly to identify those properties that are universal – and to better understand how the particular properties of the phonetic systems of spoken or signed languages might influence the abstract units that comprise a phonological grammar. The first goal might be called the 'phonological universals' question, since it is concerned with the common properties shared by signed and spoken languages, and the second the 'modality' question, since it addresses the extent to which the visual/gestural nature of sign languages and the auditory/aural nature of spoken languages affect the grammars of those languages.

During the first phase of research on sign language phonology, the focus was primarily on the 'phonological universals' question. Some commonalities between signed and spoken languages that were brought to light during this period are the following (this is not an exhaustive list, see Corina and Sandler, 1993; Brentari, 1995). First, just as in spoken languages, there is an autonomous prosodic hierarchy that uses the syllable (Perlmutter, 1992), the prosodic word (Sandler, 1999), the phonological phrase (Nespor and Sandler, 1999), and the intonational phrase (Wilbur, 1994; Nespor and Sandler, 1999). Second, in the community of deaf children born to deaf parents, the *time course* of phonological acquisition has been shown to unfold in the same manner as *that* of hearing children who are natively acquiring a spoken language. For example, the syllable is the fundamental unit used in sign language babbling, just as it is in spoken languages (Pettito and Marentette, 1991). Moreover, as Jakobson (1968 [1941]) predicted for spoken languages, the appearance of less marked phonological properties is earlier and the appearance of more marked ones later in sign languages as well (Klima and Bellugi, 1979); Boyes Braem, 1990; Marentette and Mayberry, 2000). Third, there is dialectal variation in sign languages from one region to another within a sign language (Lucas, 2001), and sign languages change historically over time via principles of diachronic change (Frishberg, 1975). Finally, elements are borrowed from one sign language to another as well as from the surrounding majority spoken (and written) linguistic community (Battison, 2003 [1978]; Brentari, 2001). Within the past 10 years, work on sign language has turned more toward what was referred to in the first paragraph as the modality question. There are several

Sign Language: Phonology

D Brentari, Purdue University, West Lafayette, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

It is taken as given that phonology refers to a level of that grammar that combines a finite number of meaningless features into an infinite number of pronounceable utterances and that the communication modality in which this phonology is expressed can be either auditory/vocal (i.e., a spoken language) or visual/gestural (a sign language). An important, but distinct, subject of investigation is whether phonology refers to the auditory signals and gestures of the vocal apparatus in a spoken language or the visual signals and gestures of the hands and body in a signed language with the phonological grammar. With this in mind, two of the primary theoretical goals of studying the phonology of sign languages are to put into sharp contrast those aspects of phonology that are shared by all languages, both signed and spoken – and thereby be able more clearly to identify those properties that are universal – and to better understand how the particular properties of the phonetic systems of spoken or signed languages might influence the abstract units that comprise a phonological grammar. The first goal might be called the 'phonological universals' question, since it is concerned with the common properties shared by signed and spoken languages, and the second the 'modality' question, since it addresses the extent to which the visual/gestural nature of sign languages and the auditory/aural nature of spoken languages affect the grammars of those languages.

During the first phase of research on sign language phonology, the focus was primarily on the 'phonological universals' question. Some commonalities between signed and spoken languages that were brought to light during this period are the following (this is not an exhaustive list, see Corina and Sandler, 1993; Brentari, 1995). First, just as in spoken languages, there is an autonomous prosodic hierarchy that uses the syllable (Perlmutter, 1992), the prosodic word (Sandler, 1999), the phonological phrase (Nespor and Sandler, 1999), and the intonational phrase (Wilbur, 1994; Nespor and Sandler, 1999). Second, in the community of deaf children born to deaf parents, the *time course* of phonological acquisition has been shown to unfold in the same manner as *that* of hearing children who are natively acquiring a spoken language. For example, the syllable is the fundamental unit used in sign language babbling, just as it is in spoken languages (Pettito and Marentette, 1991). Moreover, as Jakobson (1968 [1941]) predicted for spoken languages, the appearance of less marked phonological properties is earlier and the appearance of more marked ones later in sign languages as well (Klima and Bellugi, 1979); Boyes Braem, 1990; Marentette and Mayberry, 2000). Third, there is dialectal variation in sign languages from one region to another within a sign language (Lucas, 2001), and sign languages change historically over time via principles of diachronic change (Frishberg, 1975). Finally, elements are borrowed from one sign language to another as well as from the surrounding majority spoken (and written) linguistic community (Battison, 2003 [1978]; Brentari, 2001). Within the past 10 years, work on sign language has turned more toward what was referred to in the first paragraph as the modality question. There are several

Figure 1 A two-movement (disyllabic) ASL sign that demonstates the 'A' handshape and the three-dimensional planes used as places of articulation. (Reproduced with permission from Mouton de Gruyter.)

Figure 2 The ASL sign CANDYwith [flexed] index finger and twisting movement at the cheek. (Reproduced with permission from Mouton de Gruyter.)

ways in which signed and spoken languages are fundamentally different in their phonological organization. Each of these comprises a separate section of this article, and a possible source for these differences is proposed. But before this comparison is made, there is an important comparison internal to the phonological structure of signs that has come to light in the past 15 years.

The Categorical Nature of Sign Parameters

The five commonly accepted parameters (or feature classes) of sign languages are the following:

- Handshape: properties of the fingers and joints of the hand in forming a particular handshape, e.g., a 'fist' handshape with *all* fingers *flexed* at the joints (see Figure 1, the ASL sign DESTROY)
- Movement: how and where the hand moves – e.g., a twisting movement of the hand (as seen in Figures 2 and 3 in the ASL signs CANDY and APPLE)
- Place of articulation with which the hands interact: a region on the body (such as the cheek, in Figures 2 and 3) or one of the three-dimensional planes seen in Figure 1
- Orientation of the hand: the interaction between a place of articulation and a particular part of the hand – e.g., fingertip to side of cheek (see Figure 2)
- Nonmanual behaviors: properties of the face and body (excluding the hands), such as open-to-closed mouth – e.g., the ASL sign ACCOMPLISH-EASILY (see Figure 4).

A finding that has emerged from a number of converging types of evidence about sign language phonology is that each of the parameters of a sign does have identical types of structures in the phonology.

Figure 3 The ASL sign APPLE with [extended] index finger and twisting movement at the cheek. (Reproduced with permission from Mouton de Gruyter.)

Figure 4 The ASL sign ACCOMPLISH-EASILY, demonstrating the required nonmanual behavior of the mouth closing during the articulation of the sign. (Reproduced with permission from Cambridge University Press.)

Handshape can be considered the most arbitrary and the most categorical of the sign language parameters. This means that it is comparatively easier to list a reasonably small number of handshapes based on their discrete component parts than it is to do this with movement or place of articulation. Compared with the other parameters, handshape is able to conform most closely to the formalism of binary oppositions and hierarchical representations (Sandler, 1989; Brentari, 1998). This perspective on handshape as more categorical than the other parameters is supported in the psycholinguistic literature as well. In Emmorey *et al.* (2003), handshape was found to exhibit categorical perception effects for signers (but not for nonsigners), while place of articulation failed to exhibit such effects. In studies of word segmentation judgments (Brentari, in press) and of judgments of 'similarity' between signed words (Corina and Hildebrandt, 2002), both signers and nonsigners used movement and handshape most heavily, and only signers made use of the handshape parameter in this task.

We now turn to the differences between signed and spoken languages in their phonological organization.

Dominance and Dependency within the Feature Geometry

With respect to the prominence of phonological units in a feature geometry, the position of the segment – understood here as C(onsonant), V(owel) or undifferentiated 'X' slots on the timing tier – is fundamentally different in signed and spoken languages. The difference can be stated as follows (van der Hulst, 2000; Brentari, 2002): In a spoken language hierarchy of units, segments are autonomous from features, dominate features, and can create minimal contrast (i.e., segments >> features). In a sign language hierarchy of phonological units, feature information predicts and dominates segmental units (i.e., features >> segments). This can be seen in the use (or lack of use) of segmental orders to create new words and in the unit upon which minimal pairs are based.

Regarding segment order, the degree of variability in order and content of segments in spoken words is greater than in signed words. 'Teen' and 'neat' are different, unrelated words in English that use the same phonological segments in different orders. In ASL, this type of contrast is severely limited (Channon, 2002a, 2002b). Except in the case of compounds, the order of handshapes in a sign is largely predictable; the only handshape that can precede or follow a (closed) handshape is its (open) variant, and the only place of articulation that can precede or follow a specified place is an allophonic place within that region. Most counterexamples to this generalization – i.e., pairs of signs, similar to 'neat'/'teen,' with contrasting order in ASL – are signs with opposite meanings, such as TAKE-UP (HS1 → HS2; Figure 5)

Figure 5 A one-handed form of the ASL sign TAKE-UP [a course]. (Reproduced with permission from MIT.)

Figure 6 A one-handed form of the ASL sign DROP [a course]. (Reproduced with permission from MIT.)

vs. DROP (HS1 → HS2; Figure 6); IMPROVE (POA1 → POA2) vs. GET-WORSE (POA2 → POA1). This shows that segment order might have a morphological rather than a phonological use.

Minimal Pairs

The unit upon which most minimal pairs are based also shows a lack of reliance on the segment. Minimal pairs in ASL involve the unit of the entire word, rather than the syllable or the segmental unit. In the schematic structural representations in Figure 7,

Figure 7 Representations using segmental (left) and autosegmental (right) models to represent a minimal pair. The segmental representation incorrectly indicates 2 instances of the same handshape, while the autosegmental correctly indicates only 1 instance (cf. Sandler, 1986; Brentari, 2002).

a schematic structural representation, you can see two different ways that CANDY and APPLE (Figures 2 and 3) might be represented, but there is consensus among sign language phonologists that the representation on the right is the correct representation, with the handshape an independent part of the representation that spreads across the entire word domain.

The Syllable in Signed and Spoken Languages

The syllable has been demonstrated to be a fundamental unit in word segmentation in spoken languages. There is evidence that when properties, such as vowel harmony, that are expressed at the word level are put into conflict with stress, the syllabic cue of stress is more heavily relied upon. Moreover, words in most spoken languages have binary metrical feet, where feet often are defined in terms of syllables. All of these factors indicate that there is at least a statistical preference for words to be longer than one syllable in spoken languages. This contrasts with the relatively low use of the syllable in sign languages. The majority of ASL monomorphemic signs are one syllable (93%, according to the dictionary Stokoe *et al.*, 1965). However, within the 7% of disyllabic lexical items, there are four types (Brentari, 1998): (i) those that repeat the movement in some form with no change in handshape (e.g., CHILDREN); (ii) those that repeat the movement in some form with an allophonic change in handshape on one movement only (e.g., DESTROY, Figure 1); (iii) those with two distinctive movements with an allophonic change in handshape (e.g., JUMP); and (iv) those that repeat the movement in some form with a contrastive change in handshape (e.g., BACKGROUND). The syllable does have one important role, however. As argued in Perlmutter (1992) and Brentari (1998), the

Table 1 Comparison of 3 key factors in visual and auditory processing

	Vision	*Audition*
a. Speed of signal transmission	186 000 mps	1089 ft/sec
b. Peripheral temporal resolution	25–30 ms	2 ms
c. Spatial arrangement information	peripheral	non-peripheral

syllable is the unit that best captures the coordination of the timing of handshape with movement in such forms. For example, a handshape change such as the one in DESTROY (Figure 1) is coextensive with an individual movement; it does not extend throughout an entire disyllabic sign.

Effect of Signal Processing

The differences between the phonology of signed and spoken languages seen in the earlier sections of this article, such as a deemphasis of the syllable and the segment, may be characterized as a tendency toward simultaneous rather than sequential structure within words. This may be due to the relative strengths inherent in the design of the visual and auditory systems. A few differences between vision and audition are given in Table 1.

Many aspects of *vertical* and *horizontal* processing take place in both vision and audition. 'Vertical processing' is a cover term for our ability to process various input types presented roughly at the same time (e.g., pattern recognition, paradigmatic processing); 'horizontal temporal processing' is our ability to process temporally discrete inputs into temporally discrete events (e.g., ordering and sequencing of objects in time, syntagmatic processing). Aside from the simple 'speed of transmission,' there is also a difference between audition and vision in the time required for a subject to detect temporally/sequentially discrete stimuli – a *horizontal* processing task, called 'threshold of flicker fusion' in vision and 'peripheral temporal resolution' in audition. Humans can perceive two auditory stimuli as discrete when they are separated by an interval of only 2 ms, while the visual system requires at least a 20 ms interstimulus interval to perceive two visual stimuli as discrete. The advantage here is with audition. In contrast, when comparing *vertical* processing tasks in audition and vision, 'spatial arrangement' vision has the advantage. Vision can take advantage of light waves reflected not only from the target object but also from other objects in the environment, thereby making use of 'echo' waves – i.e., those reflected by the target object onto other objects. These echo waves are available simultaneously with the waves reflected from the target object to the retina. The same echo phenomenon in audition is available to the listener much more slowly. Only after the sound waves produced by the target object have already struck the ear will echo waves from other objects in the environment do the same. The result of this effect is that a three-dimensional image is available more quickly in vision, due in part to the speed at which light travels. Moreover, the localization of visual stimuli is registered at the most peripheral stage of the visual system, at the retina and lens, while the spatial arrangement of auditory stimuli can be inferred only by temporal and intensity differences of the signal between the two ears.

Well-designed research that compares the impact of differences in peripheral systems and signal processing on the phonology of signed and spoken languages will bring us closer to understanding the phonological capacity that all humans share.

The field of psycholinguistics strives to understand the relationship between linguistic structure and cognitive processing. Linguistic, and especially psycholinguistic, research of signed languages is still in its infancy. It has only been approximately 30 years since American Sign Language (ASL) has been regarded as an autonomous and linguistically complex language (Klima and Bellugi, 1979). Additional descriptions and analyses of signed languages from around the world have emerged over the years, rapidly broadening the sign language linguistics landscape (Brentari, 2001). In his seminal works, William Stokoe described each sign according to the shape of the hand (hereafter *handshape*), the location in relation to the body, and the movement in space produced during its articulation (Stokoe *et al.,* 1976). These separate dimensions of sign formation came to be known as 'parameters.' Subsequent work by Battison (1978) argued for the inclusion of hand shape orientation as an additional parameter. Over the last few decades, researchers have elaborated on these initial descriptions of sign structure, proposing models that encompass phonological, morphological, syntactic, semantic, and pragmatic properties of signed languages. Descriptions cast within these formal linguistic models help elucidate those properties of sign languages that are common to all human languages, as well as to isolate those properties that reflect the unique structure of human languages that are articulated manually and perceived visually.

Single Sign Recognition

The field of psycholinguistics strives to understand the relationship between linguistic structure and cognitive processing. Linguistic, and especially psycholinguistic, research of signed languages is still in its infancy. It has only been approximately 30 years since American Sign Language (ASL) has been regarded as an autonomous and linguistically complex language (Klima and Bellugi, 1979). Additional descriptions and analyses of signed languages from around the world have emerged over the years, rapidly broadening the sign language linguistics landscape (Brentari, 2001). In his seminal works, William Stokoe described each sign according to the shape of the hand (hereafter *handshape*), the location in relation to the body, and the movement in space produced during its articulation (Stokoe *et al.,* 1976). These separate dimensions of sign formation came to be known as 'parameters.' Subsequent work by Battison (1978) argued for the inclusion of hand shape orientation as an additional parameter. Over the last few decades, researchers have elaborated on these initial descriptions of sign structure, proposing models that encompass phonological, morphological, syntactic, semantic, and pragmatic properties of signed languages. Descriptions cast within these formal linguistic models help elucidate those properties of sign languages that are common to all human languages, as well as to isolate those properties that reflect the unique structure of human languages that are articulated manually and perceived visually.

Single Sign Recognition

As in spoken language psycholinguistics, much of the literature on sign language psycholinguistics has sought to uncover the structure of the lexicon, and the processes governing the access of lexical items stored therein. Most contemporary models of spoken and

written word recognition conceptualize lexical access as a matching processing between a perceptual signal that accrues over time, and potential lexical candidates stored in memory (e.g., Cohort model, Neighborhood Activation model, and TRACE). (For a review, see Jusczyk and Luce, 2002). Competitive activation among lexical candidates ultimately yields a single word percept. Questions that are especially relevant to sign language psycholinguistics, therefore, include how the *physical* properties of the sign language signal affect the way the lexicon is initially accessed en route to word recognition, and what organizational principles dictate how signs are stored within the lexicon.

In spoken languages, word recognition is achieved through the mapping of the acoustic speech signal received by the ear onto stored mental representations of word forms in the listener's mind. The mapping process unfolds in time as the acoustic signal of the word accrues, and is thought to be mediated by psychological representations that, in part, rectify variances in the signal due to coarticulatory factors (e.g., allophonic variation) and cross-speaker differences. The details of the initial phonetic mapping, the structure of the representations, and the structure of the mental lexicon have been elucidated by psycholinguistic research. Well-accepted findings include lexicality and word frequency effects, context effects including semantic and form-based priming, and neighborhood effects.

Lexicality effects refer to the finding that words are recognized faster than non-words. This basic finding suggests that the presence of a mental representation (i.e., a known word) provides a target for a search though the lexicon, whereas the lack of a representation engenders an exhaustive and unfilled search and thus incurs a processing disadvantage. *Word frequency effects* suggest that words that are highly frequent in the language (e.g., *baby*) are recognized faster than low-frequency words (e.g., *dragon*). Psycholinguists have proposed a thresholding account of these data, with highly frequent words having a lower resting threshold, thus requiring less information in order to be recognized. *Context effects* may occur in time, whereby a word that has been previously encountered may affect the subsequent processing of incoming words. For example, the recognition of the word *cat* is faster if subjects previously heard the word *pig* rather than an unrelated word such as *pail*. This robust effect is known as *semantic priming*. These data suggest that the lexicon is structured along a semantic dimension, such that semantic features may be shared between entries and thus may be coactivated, leading to speeded processing of related entries.

While only a few psycholinguistic studies of on-line processing in signed languages exist (see Emmorey, 2002 for a recent review of psycholinguistic studies of ASL), there is a growing body of literature confirming that factors affecting spoken word recognition also influence the recognition of signed language sign. For example, the importance of the lexical status of a sign form was demonstrated in a study in which participants were required to make a lexical decision about a target sign, after first being primed by a related sign or sign-form. Reaction times were significantly slower to formationally possible but non-exisiting ASL signs than to real ASL signs (Corina and Emmorey, 1993). Similarly, Dye and Shih (2005) reported data from native users of British Sign Language that showed lexicality effects (with slower responses to non-signs) in that language.

From Signal to Representation

Although signs and spoken words are formationally quite different, we have reason to believe that words in each modality unfold in time in a lawful fashion, and that accessing lexical representations may vary as a function of sublexical properties. For example, in a study by Emmorey and Corina (1990), signs were partitioned into 33 millisecond parts and presented to participants in a cumulative procedure. The location of the sign was identified first, followed quickly by the hand shape, and finally, the movement. Signs located in neutral space were recognized before those located upon the face, presumably because the target location of the sign was achieved earlier for neutral space signs. In addition, it was observed that signers could anticipate changes in signs that included a hand shape change prior to full articulation of the hand shape. These data are important as they demonstrate that in sign recognition, as is seen with spoken language, coarticulatory factors may assist word identification.

Finally, these studies confirmed that signs, though typically longer in duration than spoken words, were identified very quickly. In contrast to spoken English words in which approximately 83% of a word must be heard before identification occurs, sign identification occurred only after approximately 35% of the sign form had been seen. Two factors that may account for this finding include the relatively greater simultaneous packaging of phonological information within a sign and the fact that few signs share an initial phonological shape, leading to a reduced number of competing lexical items (i.e., reduced initial cohort size).

Form-Based Structure of the Lexicon

While the lexicon may be organized along a semantic dimension such that words sharing a meaning

relation prime one another, there is substantial support for the findings that structural properties of words influences processing. For example, the processing of the word *cat* can be affected by a previous encounter with a similar sounding word like *mat* more than an unrelated word like *lip*. This suggests a further dimension of lexical organization that honors a structural relationship between words (for example the phonological status of shared 'rime.')

Frequency effects and semantic context effects speed recognition. In contrast, structural relations (e.g., phonological composition of words and lexical neighborhoods) have been reported to typically produce inhibitory effects. Lexical decision studies have sought to establish processing effects based upon shared formational similarity (i.e., sign sharing one or more parameters), but have reported discrepant findings. For example, Corina and Emmory (1993) reported *inhibitory* effects for targets sharing an articulatory location with primes, no effects for shared hand shapes and a facilitatory effect for movement. More recently, Corina and Hildebrandt (2002) investigated movement and location priming activation at 500 and 100 milliseconds interstimulus interval (ISI) lags, and found no evidence of phonological priming for either movement or location at the 500 ISI lag, though inhibitory non-significant trends (movement $p < .064$, location $p < .088$) were observed both for location and movement at 100 ISI lag. Further, Dye and Shih (2005) found some evidence of facilitatory phonological priming in native signers for signs that shared a common location and/or location and movement. Importantly, these effects were not observed when primes were non-signs, suggesting these source of effects were not pre-lexical.

The inconsistent findings in structural priming studies of signed languages may reflect different sources of activation. The studies of Corina and Emmory (1993) and Dye and Shih (2005) that report facilitation document unusually long reaction times for sign target detection (>1100 msec), while the study that reported inhibition has reaction times in the 800 msec range. There is a growing consensus in the psycholinguistic literature that these longer reaction times may reflect post-lexically mediated or controlled processing strategies, while inhibition represent the effects of automatic priming. That is, these inhibitory effects reflect lexical rather than post-lexical access.

A related and well-known factor influencing lexical access across both written and spoken language modalities is the composition of the candidate set of lexical entries from which a single target form must emerge. In spoken languages these effects are conceptualized as owing to competition among formationally similar lexical entries – so-called *neighborhood effects*. The metric of lexical neighborhood similarity has been traditionally defined in terms of phonological properties in studies of spoken words and orthographic properties in studies of written words. For example, Luce and Pisoni (1998; see also Luce, 1986) derive neighborhood similarity by considering the number of words that could be obtained by a single phoneme substitution, addition, or deletion. Numerous studies have demonstrated that these similarity properties influence word recognition, as shown in the accuracy of perceptual identification, latencies in naming and lexical decision tasks, and priming effects, both in spoken and visual word recognition (for discussion see Jusczyk and Luce, 2002).

The frequency of individual lexical items may also interact with properties of similarity. Importantly, the effects of similarity and word frequency have been observed across many spoken languages. A general characteristic of these effects, based upon the spoken word recognition literature, is that lexical access tends to be inhibited as similarity increases, especially when lexical frequency is held constant. A series of studies conducted with Lengua Signos Espanol (LSE) have examined the interaction between sign similarity and frequency (Carreiras *et al.,* submitted). As sign frequency counts are unavailable for most signed languages, this measure was formalized as a familiar rating based upon how often a particular sign was used. Lexical similarity was evaluated using the Hamburg Sign Language Notation System (Prillwitz *et al.,* 2004) whereby the degree of similarity for the parameters of location and hand shape was calculated by counting how many signs were produced in a particular location or articulated with a specific hand shape. These studies reveal that for neighborhoods defined by location, low-frequency signs are recognized faster in non-dense neighborhoods. A different pattern was observed for neighborhoods defined by hand shape. Here, low-frequency signs were recognized faster in dense neighborhoods.

Several explanations for the processing differences for location and hand shape are offered. In many theoretical models of sign structure, hand shapes are represented as multi-featured compositional and hierarchically-ordered entities that serve as auto-segments within skeleton-based phonological treatments (Corina and Sandler, 1993). Featural representations of location tend to be far less compositional, often adopting a unitary or privative representation such as [shoulder] for a sign articulated on or near the shoulder (Brentari, 1998). These variations in richness of representation may differentially impact lexical activation. It is interesting to note that in spoken work there is some evidence for word onset

information producing inhibitory effects (e.g., Luce and Pisoni, 1998; Vitevitch and Luce, 1998). As noted above in the gating studies of sign recognition, location was the first parameter to be accurately and consistently identified during the unfolding of a sign, followed by hand shape. This is not to suggest that location serves as a syllabic onset in sign languages, but rather that there may be a special status of first recognized word/sign elements across languages.

Effects of Language Experience

A different approach to the study of the underlying structural properties of signs and the sign lexicon is through the study of *phonological awareness* in deaf signers. Phonological awareness reflects an understanding that words are not unsegmented wholes, but are made up of component parts. Some structural groupings in spoken languages have a special status that can often be observed in stylized language usage such as poetry, language games and song. For example, words that rhyme (e.g., *juice-moose*) are generally appreciated as more similar-sounding than words that share onsets (e.g., *juice-june*).

Signed languages exhibit similar privileged groupings. Controlled studies reveal that similarity judgments of signs sharing two sign parameters (i.e., hand shape and movement) produced much more consistent judgments that signs sharing only one parameter (Hildebrandt and Corina, 2002). Both deaf and sign-naive subjects judge signs that share movement and location as the most similar, indicating that this combination of parameters enables a robust perceptual grouping. This fact accords well with the observation that languages commonly capitalize on robust perceptual distinctions as a basis for linguistic distinctions. Interestingly, however, response patterns of the deaf native signers indicate that under some circumstances, tacit knowledge of ASL syllable structure may override purely perceptual factors. The findings that the combination of movement and location provides a robust perceptual grouping accords well with theories of syllable structure in ASL that have proposed that the combination of movement and location properties serve as the skeletal structure from which syllables are built, and that movement is the most sonorous element of the sign syllable (see, for example, Sandler, 1993).

The effects of language experience on the perception of signing are further illustrated in the studies investigating the phenomena of *categorical perception*. In the spoken language domain, this phenomenon refers to the finding that speech stimuli are perceived categorically rather than continuously despite a continuous variation in form (Liberman *et al.*, 1967). The principle of categorical perception helps explain how listeners may resolve the many-to-one mapping between continuous acoustic patterns and discrete phonological categories. Initially, the phenomenon of categorical perception was taken as evidence for a hard-wired, language-specific mechanism, but more recent work has placed the phenomenon within the framework of a general psychophysical mechanism that may be observed over a variety of non-language domains.

Studies of categorical perception for phonological parameters in ASL have been conducted for place of articulation, hand shape, and facial expressions in signers and non-signers. Recently, categorical perception was found for the parameter of hand shape, but not place of articulation (McCullough *et al.*, 2000), an effect that was limited to deaf signers. This indicates that linguistic knowledge can influence perceptual judgments. While it has been demonstrated that hearing non-signers exhibit categorical perception for emotional facial expressions (Calder *et al.,* 1996), the study of categorical perception for facial information is interesting in signed languages, as facial information in ASL not only conveys emotional information about the state of the speaker, but also serves a linguistic function. Several well defined facial configurations serve to signal adverbial modulations and specify syntactic forms. Recent studies have found categorical perception of both emotional and linguistic facial expression (McCollough and Emmory, 1999) and British Sign Langauge (Campbell *et al.,* 1999). However, these effects were observed in both deaf signers and hearing non-signers, suggesting that categorical perception for facial expression is not mediated by linguistic knowledge *per se*.

Sign Language Production

As with the study spoken languages, psychological processes underlying the production of sign language have been underrepresented in the literature. However, examples of 'slips of the hand' akin to 'slips of the tongue,' have been reported in signed languages, in which semantic- and form-based errors are attested, but dual (semantic + phonological) errors are rare. For example, in a recent report of production errors in German Sign Language (Deutsche Gebaerdensprache [DGS]), 38/40 sign-substitution errors are semantically based; only one is semantically and form-based (Hohenberger *et al.,* 2002). Sign language form-based errors are manifest primarily as anticipations and perseverations. Interestingly, there is marked disparity in the frequency with which the individual sublexical form parameters are subject to error, with hand configuration being far

more susceptible to error than place of articulation and movement (Hohenberger *et al.,* 2002). These data are consistent with previous slip literature (Klima and Bellugi, 1979; Newkirk *et al.,* 1980) in which the majority of form-based errors were in hand configuration.

In a sign language production experiment (Corina and Knapp, in press), the time-course of semantic and phonological form retrieval in a visual-manual language during production was examined using a sign-picture naming paradigm, in which signers were required to articulate sign names of an object while observing an overlay of a distractor sign. This Stroop-like task found that native signers of ASL exhibit longer naming latencies in the presence of semantically-related sign distractors than in the presence of unrelated distractors at early, but not late, stimulus onset asynchronies (SOAs). In contrast, phonologically-related stimuli produce naming facilitation both early and late in the naming process, but effects vary by degree and type of phonological relatedness. We observed different amounts of interference between distractors that shared one, two, and three parameters with the target, with greatest effects observed when the sign target to be articulated and the interfering stimulus shared both movement and location parameters. Interestingly, the combination of location and movement was an important factor in the lexical decision experiment of Dye and Shih (2005). As noted previously, location and movement components of signs are linguistic categories that may comprise the skeletal structure of a sign.

Morphology

Morphological theories are formal statement about how word forms are built. Traditional approaches provide accounts of how new words are adopted into the existing lexicon (i.e., coinage), the relationships between word forms that change grammatical category and thus extend meaning usage (i.e., derivational morphology), and how word forms adapt in the face of syntactic phenomena (inflectional morphology).

Psycholinguistic studies of sign language morphology have been largely driven by the fact that morphological processes do not easily fit into a traditional segment-based approach. In contrast to spoken languages, in which morphological forms are commonly created by prefixing or suffixing onto a stem, many of the morphological form changes observed in signed languages are non-concatenative. Under morphological inflection, the entire base form undergoes complex movement modulations.

Consider, for example, the morphological changes that affect a verb like *tell*. In the citation form of this sign, the extended index finger of the otherwise closed hand shape touches the chin with the palm facing the signer. It moves forward in a straight path via the extension of the elbow to approximately a 120-degree angle. In one aspectual inflection that signals intensity or forcefulness, we find the elbow extension reduced, and an increase in movement velocity. A temporal inflection, giving rise to a meaning that this action occurred again and again over time, adopts an elliptical path movement that passes by the chin in repeated cycles. Inflection for grammatical number agreement may take on a sequence of repeated straight movements directed towards between two or three laterally and evenly displaced points in space. Finally, grammatical verb agreement inflections modulate the beginning and end of the path movements which in turn signal the grammatical subject and object of the sentences, respectively.

Many psycholinguistic studies of spoken language morphology have examined whether morphologically complex forms are decomposed into constituent parts or treated in a more holistic fashion. Current indications are that the degree of decomposionality may vary with the formal devices used to modulate word meaning in a specific language. The question of how complex sign forms are parsed has been dealt with in only a handful of studies. Emmorey (Emmorey *et al.,* 1991; Emmorey, 1991) investigated the organization of the lexicon for morphologically complex forms using a repetition priming experiment. Here, a morphologically inflected sign was used as a prime, and a lexical decision was made about its uninflected form. These studies found that whereas sign primes inflected for aspect (e.g., habitual, continual) did produce facilitation in the recognition of the associated uninflected stem, signs inflected for grammatical agreement (e.g., dual, multiple, reciprocal) did not prime their citation forms. Emmorey (2002) has suggested that differing degrees of productivity may effect the lexical representation of morphologically complex forms in ASL. The interplay between the number of verb types that participate in a particular inflectional process may influence the association between related forms in the lexicon. For example, more verb forms can be marked with the habitual inflection than the reciprocal inflection.

Syntax

Syntax refers to a level of language form that specifies the interrelationship between words in a sentence. Formal studies of syntax reveal universal and language-specific patterns and constraints that reliably

contribute to interpretation of the sentence meaning, especially those specifying thematic roles. Psycholinguistic studies of syntactic processing strive to understand how these structured patterns are exploited during on-line comprehension of sentences, and how this information is combined with word meaning to give rise to a conceptualization of the intended message.

Early spoken language studies examined the psychological reality of clause boundaries and syntactic complexity (Garrett *et al.,* 1996). More recent studies have attempted to document the precedence of sentence interpretation as it unfolds in time, with some suggesting a leading role of syntactic over semantic properties. Other studies have examined how structural dependencies in a sentence are instantiated – for example, the integrative processes by which a noun and its associated pronoun are coupled in sentences such as 'John went to the store and he bought some bread.' The few studies of syntactic processing in signed languages have focused on the phenomenon of co-reference, exploiting the unusual means by which pronouns and their noun antecedents are associated. Specifically in signed languages like ASL, a signer may associate a noun with a specific location in articulatory space (typically on a horizontal plane in front of the signer) with a later indexic point to this space signaling a co-referential relationship. Thus in the sentence above, the proper noun John may be articulated in a right-sided location in neutral space, a subsequent point to that same location would signal the antecedent 'John.' In many theories of sign language grammar this pointing sign is considered a pronoun.

Spoken language studies have found that at the time one encounters a pronoun in a sentence one can find evidence that its noun antecedent has been reactivated. Using a probe recognition technique Emmorey and colleagues found evidence for antecedent re-activation during sign comprehension that was similar to that observed for spoken languages. A semantically-related probe sign that followed the pronoun was recognized faster than a semantically inconsistent sign. The authors also explored several sign language-specific aspects of co-reference. For example, the re-activation was noted even when the grammatical co-reference was signaled by verb agreement rather than by an overt pronoun, thus providing a psycholinguistic validation of the theoretically motivated analysis of null-pronoun phenomena in ASL (Emmorey and Lillo-Martin, 1995). In addition, Emmorey, Corina, and Bellugi (1995) examined whether the spatial location of the probe interacted with the entailed semantic relationships. They found that the consistency of the spatial location of the probe item did not influence response times. That is, while a semantically (and co-referentially) appropriate related probe sign was recognized faster than a semantically inconsistent sign, these recognition times were not modulated by absolute spatial location of the probe (which could appear in the same location as the pronoun [and antecedent] or a different location). Interestingly, this lack of spatial effect was observed only in sentences in which the spatial locations signaled grammatical relations. In contrast, when the spatialization of the nouns and pronouns made reference to actual topographic relationships (i.e., real world space, e.g., 'chair located to the left of a table'), the consistency between the probes and the spatially established referents did positively influence reaction times. This finding is consistent with a theoretically-motivated distinction between grammatical space and topographic use of space in sign. In sum, these studies have found that the same processing mechanisms are required to interpret coreference in signed and spoken languages, but for signed languages, the type of information represented by the spatial location can influence how coreference relations are processed (Emmorey, 2002).

In conclusion, while psycholinguistic studies of signed languages are just beginning, preliminary findings indicate a great deal of commonality between the factors underlying the recognition, access, and structure of items in the mental lexicon, as well as the parsing and interpretation of morphological and syntactic structure. However, some unique and subtle processing differences have been found between spoken and signed languages, thus confirming that the modality of language expression can affect the final form of mental structure of language.

Sign Language: Semiotic Approaches

W C Watt, University of California, Irvine, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

'Sign languages,' or 'gestural languages,' mostly arise in place of voice languages when voice languages are unavailable to people because they are profoundly deaf, because they speak different languages that are mutually unintelligible, or because speaking is barred by custom. ('Gestures' in this context include facial expressions.) Examples are the gestural language of the American deaf – 'Ameslan' or 'ASL' (American Sign Language) – and the gestural languages of the American Plains Indians and of certain monks sworn to silence. A gestural language is a language just as English is; lesser gestural systems such as the signals used by traffic cops or landing signal officers on aircraft carriers do not offer a sufficiently rich repertoire of signs – or above all, a syntax – to enable their users to convey whatever they wish. A landing signal officer can convey 'OK to land' but not, as English can so easily, 'A two-mile-long aircraft carrier has just been commissioned that can land 747s.'

Because gestural languages mainly use hand gestures to produce their sentences and eye recognition to receive them, they differ significantly from voice languages produced by the vocal tract and received by the ear. For example, voice languages convey much by intonation and stress – thereby distinguishing between 'You've been to Paris' and 'You've been to *Paris*?' – while in a gestural medium, these are conveyed by gestures alone.

True gestural languages must be distinguished, not only from the communications available to traffic cops and the like, but also from another limited medium, the 'fingerspelling' that the deaf sometimes resort to. Fingerspelling, whether assigning areas on one hand to stand for a letter to be pointed at by the forefinger of the other (Dalgarno, 1680), or more directly indicating the letters with finger configurations (often mimicking letter shapes) (Stokoe, 1974), is only a way of conveying the spelling of some voice language (e.g., English). In contrast, Ameslan is quite independent of American English (and differs from its British counterpart). Their autonomy is another criterion by which gestural languages can be judged 'true languages.'

Gestural languages combine partial gestures that are functionally equivalent to phonemes (West, 1960: vol. I, 9–18) to form morphemes and words. These partial gestures are variously called 'cheremes' or 'kinemes' and are syntactically structured into sentences. Thus, the Ameslan morpheme 'girl' is gesturally conveyed, rather than by the four phonemes /g/, /^/, /r/, and /l/, by three concurrent 'cheremes' characterized as 'drawing down,' 'the ball of the thumb,' and 'along the cheek' (Nöth, 1990: 284). Despite their structural similarities, however, other gestural languages typically have less expressive power than those of the deaf.

Gestural languages have been studied in depth by linguists, other semioticists, amateur and professional anthropologists, psychologists, and neurologists, whether they are used by the deaf (e.g., Bellugi and Studdert-Kennedy, 1980, esp. 29–40, 115–140, 291–340), by people lacking other inter-tribal communicative means (Umiker-Sebeok and Sebeok, 1978), by people who must abjure speech when orating stories or rituals (West, 1960: vol. II, 9, 62, 68), or by people for whom speech is taboo, such as certain monks (Umiker-Sebeok and Sebeok, 1987) and newly widowed Aboriginal women (Kendon, 1980).

Sign Language: Syntax

D Lillo-Martin, University of Connecticut, Storrs, CT, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

A major reason for interest in sign language syntax is the light it can shed on proposed universals of grammar. It is well established on the basis of spoken language research that there are consistent regularities across languages in the domain of syntax. There are also clusters of properties shared by subgroups of languages. With the advent of research on sign languages, it is possible to test the hypothesis that the principles are linguistic universals, and the systematic variability can be captured by parameters. If the same constraints apply to sign languages as to spoken languages, then it can be concluded that these are intrinsic to language. On the other hand, if signed and spoken languages display different properties, then the properties must be attributed to modality.

Discourse Orientation

A large number of studies have concentrated on determining the basic word order of a particular sign language, or, in fact, whether a basic order can even be determined. The question has been of interest because most researchers have concluded that the sign language they are investigating permits considerable variation in word order, in a way very similar to that found in the so-called Discourse Oriented languages, including Chinese and Russian (*see* **Sign Language: Discourse and Pragmatics**). In most cases a basic or underived order has been determined (e.g., SVO in American Sign Language (ASL), Brazilian Sign Language (LSB), etc. and SOV in German Sign Language (DGS), Japanese Sign Language (NS), etc., as illustrated in (1)). However, it seems that sign languages in general productively employ devices for presenting information in a different order determined by discourse factors, such as presenting old information (topic) before new information (comment) (as illustrated in (2)) (*see also* **Sign Language: Transcription, Notation, and Writing**).

(1) (a) JOHN EAT APPLE SVO order, used in ASL
(b) JOHN APPLE EAT SOV order, used in DGS
'John ate an apple'

(2) JOHN, I LIKE (t) object in topic position
'John, I like.' / 'I like John.'

In addition to evidence from the contexts in which various orders are used, researchers have noted the presence of specific non-manual markers used when the order is something other than the basic (*see also* **Nonmanual Structures in Sign Language**). Commonly (though not universally) this includes raised brows in the facial expression accompanying topics, which are also set off from the rest of the sentence by a prosodic break, including a hold and/or pause and a change of the facial expression.

Another characteristic some sign languages share with 'Discourse Oriented' languages is a special position for focused, or prominent, elements, which in ASL and LSB is the sentence-final position (as illustrated in (3)). Not as much attention has been paid to the possible existence of a particular position for focus across sign languages, although the final position is used for commonly focused elements such as negatives and WH-elements in many sign languages (*see also* **Sign Languages of the World**). Further research is needed to determine whether the existence of a focus position and/or the placement of such a focus position varies across sign languages.

(3) (a) focused elements in final position
(br) JOHN LIKE WHO, MARY
'Who John likes is Mary.'
(b) JOHN READ CAN
'John really CAN read.'

In addition to discourse motivation for word order changes, order may change in the presence of certain linguistic elements, such as verbal agreement (*see also* **Sign Language: Morphology**). When agreement is present, it provides evidence for identifying the verb's subject and object, and changes in word order are possible (see example (4)); put another way, verbal morphology licenses syntactic reordering rules. Whether to account for such reordering in the terms of scrambling or some other syntactic movement operation is not yet clear.

(4) SOV order used with agreement
GIRL IX-a BOY IX-b a-HELP-b
'The girl helped the boy.'

Another way in which sign languages are 'discourse oriented' is in the use of null arguments. Arguments of verbs marked for agreement may freely be non-overt. When verbs are not marked for agreement, arguments may also be dropped, as in languages like Chinese.

Syntactic Movement and Constraints

There has been considerable controversy over the direction of WH-movement in several sign languages,

since WH-elements can appear in sentence-initial position or sentence-final position (as illustrated in (5)).

(5) (a) WHAT ANN BUY (wh) — Sentence-initial WH-object
'What did Ann buy?'

(b) BUY CAR WHO (wh) — Sentence-final WH-subject
'Who bought a car?'

Some researchers have proposed that movement to the sentence-final position indicates that true WH-movement is rightward. An analysis that maintains that WH-movement is to the sentence-initial position, making the sentence-final WH-elements part of the more general process of focus, is able to account for a wider range of data.

An important source of data on universals of spoken language concerns constraints on syntactic movement. Whereas cyclic movement is potentially unbounded, movement is not permitted out of a syntactic 'island.' Relatively little work has been undertaken to examine the characteristics of long-distance movement in sign languages, but it has been claimed (for ASL, at least) that long-distance movement is permitted (see (6a), in which the topic 'exercise class' has moved from the embedded object of the verb 'take-up'). Movement is constrained, however, by principles such as the Coordinate Structure Constraint (see (6b), which is ungrammatical because the topic 'flower' has moved from the object of the second conjunct 'give').

(6) (a) EXERCISE CLASS, $_1$INDEX HOPE SISTER SUCCEED PERSUADE MOTHER TAKE-UP. (t)
'The exercise class, I hope my sister manages to persuade my mother to take (it).'

(b) *FLOWER, 2GIVE1 MONEY, jGIVE1. (t)
'Flowers, he gave me money but she gave me.'

Conclusion

An interesting point for future study will be to determine the extent to which sign languages themselves are parameterized. While variation is found in basic word order (at least SVO and SOV are attested), current analyses do not show variation with respect to discourse orientation. Even with this question unanswered, it is clear that the analysis of sign language syntax is quite consistent with the hypothesis that universal principles and limited cross-linguistic parametric variation apply across all languages including sign languages.

Sign Language: Transcription, Notation, and Writing

C Miller, Gallaudet University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

The complex nature of the signal in sign languages places special demands on notation systems, orthographies, and the transcription process itself. Signing is composed of visible gestures of the hands, arms, head, and body, which use space in linguistically meaningful ways. No single system has achieved the status of a standard notation for signing comparable to the IPA for spoken languages, and everyday sign language writing is the exception rather than the norm.

The process of transcribing signed data, as well as the kind of notation adopted, depends primarily on the uses and applications of the data. Different kinds of conventions are used depending on whether transcribed data are used for phonological analyses, morphological, discourse, or syntactic analyses. For the latter three, sets of fairly widespread conventions have evolved (see Klima and Bellugi, 1979). Signs are represented by upper case word glosses (joined by hyphens if more than one word is required to represent a sign's meaning), additional information usually provided in lower case. If a distinction between the two hands is important in the sentential or discourse context, the two hands are usually noted on two separate lines; information about non-manuals and mouthing, is normally placed on a line above the sign glosses.

Various systems have been developed to note the phonological structure of signs. One of the first, and the most influential, is introduced in Stokoe (1960). This notation matches handshapes to the closest letter of the American manual alphabet and ASL numbers, and uses conventionalized iconic symbols for location, movement and spatial relation. Stokoe notation has been extended and adapted since: Mandel (1981) for American Sign Language, Kyle and Woll (1985) and Brien (1992) (British Sign Language), and Bergman (1993) (Swedish Sign Language), contain some of the most extensive descriptions of such modifications, which involve adding symbols for aspects of sign structure absent in Stokoe, in particular for handshapes not in ASL or symbols that better match the local manual alphabet values (e.g., Bergman or Radutzky, 1979). Another outgrowth of Stokoe notation (Liddell and Johnson, 1989) adds detailed, word-based descriptions of movement and location structure. HamNoSys (Prillwitz and Zienert, 1990) is fairly widely used, and while similar in principle to Stokoe notation, uses iconic representations of handshape instead of letter and number symbols. Other, less widely used systems are referenced in the bibliography.

Although sign languages are rarely written down for everyday communication, two significant attempts at developing writing systems have been proposed: *Mimographie* (Bébian, 1825) and Sign Writing (Sutton, 1981), which has gained a certain following.

Software alternatives to transcription on paper have begun to appear, each of which allows computerized transcriptions to be linked to stretches of digitized video. Significant software packages are SyncWriter (Papaspyrou and Zienert, 1990), SignStream (Neidle, 2001) and Elan (Eudico Linguistic Annotator) from the Max Planck Institute in Nijmegen,

Sign Language: Transcription, Notation, and Writing

C Miller, Gallaudet University, Washington, DC, USA

The complex nature of the signal in sign languages places special demands on notation systems, orthographies, and the transcription process itself. Signing is composed of visible gestures of the hands, arms, head, and body, which use space in linguistically meaningful ways. No single system has achieved the status of a standard notation for signing comparable to the IPA for spoken languages, and everyday sign language writing is the exception rather than the norm.

The process of transcribing signed data, as well as the kind of notation adopted, depends primarily on the uses and applications of the data. Different kinds of conventions are used depending on whether transcribed data are used for phonological analyses, morphological, discourse, or syntactic analyses. For the latter three, sets of fairly widespread conventions have evolved (see Klima and Bellugi, 1979). Signs are represented by upper case word glosses (joined by hyphens if more than one word is required to represent a sign's meaning), additional information usually provided in lower case. If a distinction between the two hands is important in the sentential or discourse context, the two hands are usually noted on two separate lines; information about non-manuals and mouthing, is normally placed on a line above the sign glosses.

Various systems have been developed to note the phonological structure of signs. One of the first, and the most influential, is introduced in Stokoe (1960). This notation matches handshapes to the closest letter of the American manual alphabet and ASL numbers, and uses conventionalized iconic symbols for location, movement and spatial relation. Stokoe notation has been extended and adapted since: Mandel (1981) for American Sign Language, Kyle and Woll (1985) and Brien (1992) (British Sign Language), and Bergman (1993) (Swedish Sign Language), contain some of the most extensive descriptions of such modifications, which involve adding symbols for aspects of sign structure absent in Stokoe, in particular for handshapes not in ASL or symbols that better match the local manual alphabet values (e.g., Bergman or Radutzky, 1979). Another outgrowth of Stokoe notation (Liddell and Johnson, 1989) adds detailed, word-based descriptions of movement and location structure. HamNoSys (Prillwitz and Zienert, 1990) is fairly widely used, and while similar in principle to Stokoe notation, uses iconic representations of handshape instead of letter and number symbols. Other, less widely used systems are referenced in the bibliography.

Although sign languages are rarely written down for everyday communication, two significant attempts at developing writing systems have been proposed: *Mimographie* (Bébian, 1825) and Sign Writing (Sutton, 1981), which has gained a certain following.

Software alternatives to transcription on paper have begun to appear, each of which allows computerized transcriptions to be linked to stretches of digitized video. Significant software packages are SyncWriter (Papaspyrou and Zienert, 1990), SignStream (Neidle, 2001) and Elan (Eudico Linguistic Annotator) from the Max Planck Institute in Nijmegen,

Sign Language: Variation

C Lucas Dr, Gallaudet University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Natural sign languages are autonomous linguistic systems, independent of the spoken languages with which they may coexist in a given community. As sign languages are full-fledged autonomous linguistic systems shared by communities of users, the sociolinguistics of sign languages can be described in ways which parallel the description of the sociolinguistics of spoken languages. That is, the sociolinguistics of sign languages concerns the interrelationship of sign language and social structure. As with spoken languages, sign languages are at once used to communicate information and to define the social situation, i.e., to make statements about individual identity, group loyalties, and one's relation to one's interlocutors. The sociolinguistics of sign languages includes the study of regional and social variation, bilingualism and language contact phenomena, language maintenance and choice, language attitudes, language policy and planning, and discourse analysis (Lucas, 1995, 2001). However, it is very important to understand that while each of these areas has relevance for deaf communities, the sociolinguistics of sign is a relatively young discipline and there exist few if any empirical studies in some of these areas.

Regional and Social Variation

Regional and social variation in sign languages has been described mainly at the phonological and lexical-levels, and to a lesser extent at the morphological and syntactic levels. Variation at the phonological level involves variation in the production of the component parts of signs, such as handshape, location, palm orientation, nonmanual signals, and segmental structure. For example, the American Sign Language (ASL) signs FUNNY, BLACK, and CUTE might be produced with the thumb extended or with the thumb closed; the ASL signs BORED and DEAF might be produced with the little finger extended or with the little finger closed; the ASL sign WEEK might be produced with the palm of the dominant hand facing upward or the palm facing downward; the ASL sign KNOW might be produced on the forehead or on the cheek. Lexical variation concerns different signs for the same concept. Regional differences have been described in British Sign Language (BSL), for example, between Reading and York for the signs LEARN, SUNDAY, and WHO (Deuchar, 1984: 131). Lexical variation in BSL has also been described by Kyle and Woll (1985). Lexical variation

Natural sign languages are autonomous linguistic systems, independent of the spoken languages with which they may coexist in a given community. As sign languages are full-fledged autonomous linguistic systems shared by communities of users, the sociolinguistics of sign languages can be described in ways which parallel the description of the sociolinguistics of spoken languages. That is, the sociolinguistics of sign languages concerns the interrelationship of sign language and social structure. As with spoken languages, sign languages are at once used to communicate information and to define the social situation, i.e., to make statements about individual identity, group loyalties, and one's relation to one's interlocutors. The sociolinguistics of sign languages includes the study of regional and social variation, bilingualism and language contact phenomena, language maintenance and choice, language attitudes, language policy and planning, and discourse analysis (Lucas, 1995, 2001). However, it is very important to understand that while each of these areas has relevance for deaf communities, the sociolinguistics of sign is a relatively young discipline and there exist few if any empirical studies in some of these areas.

Regional and Social Variation

Regional and social variation in sign languages has been described mainly at the phonological and lexical-levels, and to a lesser extent at the morphological and syntactic levels. Variation at the phonological level involves variation in the production of the component parts of signs, such as handshape, location, palm orientation, nonmanual signals, and segmental structure. For example, the American Sign Language (ASL) signs FUNNY, BLACK, and CUTE might be produced with the thumb extended or with the thumb closed; the ASL signs BORED and DEAF might be produced with the little finger extended or with the little finger closed; the ASL sign WEEK might be produced with the palm of the dominant hand facing upward or the palm facing downward; the ASL sign KNOW might be produced on the forehead or on the cheek. Lexical variation concerns different signs for the same concept. Regional differences have been described in British Sign Language (BSL), for example, between Reading and York for the signs LEARN, SUNDAY, and WHO (Deuchar, 1984: 131). Lexical variation in BSL has also been described by Kyle and Woll (1985). Lexical variation

has also been looked at in New Zealand Sign Language, Italian Sign Language, Dutch Sign Language, Swiss–German Sign Language, Swiss–French Sign Language, Brazilian Sign Language, and Australian Sign Language or Auslan (Schembri and Johnston, 2004). Variation in terms of ethnicity has been looked at by Woodward (1976) and Aramburo (1989), i.e., differences between black and white signers in the USA. Gender variation has been looked at in ASL, in Chinese Sign Language, and in Irish Sign Language. However, social variation in terms of socioeconomic status (i.e., the classic Labovian type of sociolinguistic analysis) or in terms of social networks such as have been described for spoken languages has yet to be described systematically for sign languages. The variety of ASL used by deaf/blind people, known as Tactile ASL, has been investigated by Collins (2004) and similar varieties used by deaf/blind people in other countries have also been described (Mesch, 2000). Recent studies (Lucas *et al.*, 2001) have shown there to be consistent modality differences in variation, so that factors such as the grammatical function of the sign that shows variation play a more important role in explaining variation in sign languages than the immediately preceding or following environment, i.e., the sign before or after, as is commonly the case in spoken language variation.

Bilingualism and Language Contact Phenomena

There exist different kinds of bilingualism in deaf communities (Ann, 2001). For one, most deaf individuals have at least some exposure to the spoken language of the majority community in which they live. This exposure may be primarily exposure to the written form of the majority language, although in many countries a signed code to manually represent the spoken majority language has been devised, with signs invented to represent the bound morphemes of the spoken language. A discussion of bilingualism in deaf communities necessarily requires a re-examination of the term 'bilingual' as it has been used to describe spoken language communities. This is because many deaf people with a firm command of the written version of the majority spoken language choose not to use their voices because they are not able to hear themselves and hence monitor the volume or pitch of their speech. Bilingualism in deaf communities does not necessarily include **speaking** the languages in question, at least not in the way that the term 'speaking' is generally understood by linguists.

There are many occasions for language contact in deaf communities. Figure 1 presents a model of the linguistic outcomes of language contact. A fundamental distinction is made between a situation involving contact between two sign languages and a situation involving contact between a sign language and a spoken language, a distinction necessary because of the difference in modality between sign and spoken languages. Naturally, the situation is not entirely straightforward, as two sign languages may be in contact, both of which may incorporate outcomes of contact with their respective spoken languages, outcomes which may then play a role in the contact between the two sign languages.

Figure 1 Outcomes of language contact.

As can be seen from Figure 1, the outcomes of contact between two sign languages parallel the outcomes that have been described for contact between spoken languages, namely lexical borrowing of various kinds, code switching and code mixing, foreigner talk, interference, pidgins and creoles, and mixed systems (Supalla and Webb, 1995). There is much anecdotal evidence for many of these outcomes and empirical studies of the outcomes of contact between two sign languages are beginning to appear (Quinto-Pozos, 2002; Yoel, 2001). Signers borrow the signs from one language into their own; bilinguals may code-switch and code-mix elements from two sign languages; a signer may alter his signing and simplify it when signing to a nonnative, and signers may show interference from one sign language when using another. Signers have been observed to have 'accents.' As concerns contact between a sign language and a spoken language, a distinction is made between outcomes which reflect literal adherence to the spoken language criteria defined for those outcomes. For example, code switching would mean ceasing signing and beginning to talk. This is distinct from unique phenomena that occur, such as contact signing, as observed in the American Deaf community: the simultaneous production of ASL lexical forms in English word order with mouthing of English words, with the possible inclusion of inflected ASL verbs and ASL nonmanual signals. Some analyses have characterized this as a pidgin but more recent analyses find the features of this kind of signing to be inconsistent with the features of pidgins (Lucas and Valli, 1992). Fingerspelling is also a unique phenomenon, because although the forms are part of the natural sign language – i.e., the hand shape, the location, the orientation, and the segmental structure – it is a representation of the writing system of the majority spoken language (Battison, 1978). Signers in contact with languages which use the Roman alphabet fingerspell, but signers in contact with Arabic, Russian, Japanese, and Chinese also represent the writing systems of their respective spoken languages (Ann, 1998). Other unique phenomena include the English sometimes produced by the children of deaf adults (CODA-speak, Bishop and Hickes, 2005), the English of typed telephone conversations that often incorporates features of ASL (Mather, 1991), and the alteration of French places names in Langue des Signes Québécoise (Quebec Sign Language) (Miller, 2001).

Language Maintenance and Choice

Typically, the use of natural sign languages has been restricted to a very limited set of functions and has been totally excluded from the educational process. Such a sociolinguistic situation has led to the characterization of language use in the deaf community as diglossic, the majority spoken language being the H variety and the natural sign language being the L variety (Stokoe, 1969). There is a lot of evidence that some signers clearly see their natural sign language as appropriate only for intimate, informal situations, and the signed version of the majority spoken language as appropriate for public, formal situations, be the interlocutors hearing or deaf. However, as many countries around the world begin to use natural sign languages in deaf education, these sign languages are acquiring functions that they have not had before, and the spoken or signed version of the majority spoken languages may lose the functions they once had or be restricted to the functions of reading and writing. Because of the clear need in deaf communities for both a natural sign language and for some form of the majority spoken language, the situation in most deaf communities can be characterized as one of maintained bilingualism. Unlike many minority languages in a majority language situation, it would not appear that natural sign languages are in any danger of disappearing.

Language Attitudes

Language attitude studies in deaf communities concern signers' attitudes toward their natural sign language and toward the majority spoken language, attitudes toward users of the sign and spoken language, attitudes of teachers of the deaf and professionals toward natural sign languages, attitudes toward the invention and introduction of new signs, and attitudes toward the outcomes of language contact (Kannapell, 1989; Burns, 2001). Language attitude studies often reveal conflicting attitudes toward the natural sign language and the majority spoken language in a given community, as a result of lack of recognition of the status of the sign language as a viable and autonomous linguistic system. That is, pride with respect to the sign language may cooccur with an attitude that its use reveals a lower educational level or even lower intelligence in the user, while use of a signed version of the majority spoken language may be viewed as evidence of good education and superior intelligence. Pride with respect to the natural sign language may coexist with the misconception that it is not a real language or is a deficient form of the spoken majority language.

Language Policy and Planning

Language planning has been defined as deliberate decision making in response to language problems.

Deaf communities have very often been perceived as the sites of language problems, particularly as concerns the education of deaf children, for the obvious reason that deaf children do not have easy access to the spoken majority language as a medium of instruction (Ramsey, 1989; Nover, 1995; Reagan, 2001). Approaches since the 1970s have involved the invention of manual codes to represent the majority spoken language and may involve the simultaneous production of the spoken language and the sign language, referred to as sign-supported speech (Johnson *et al*., 1989). However, many deaf communities around the world are beginning to use the natural sign language of the community as the medium of instruction. All of these approaches have implications for language planning, either in the invention of manual codes for educational use, or in the use of the natural sign language for functions it has not previously had. This may entail expanding the lexicon of the natural sign language, an expansion which leads to other language-planning issues, such as whether signs should be invented for new concepts or whether new concepts should be represented with fingerspelling. Issues of access and hence of language policy and planning are not limited to deaf education. For example, providing deaf adults with full access to the business of the majority language community – i.e., media, government, the law, medical care – entails decisions as to how linguistic access will be provided. For example, whether closed captioning is preferable for television news to a sign language interpreter; whether a sign language interpreter, if provided, should use the natural sign language or a signed version of the spoken majority language; what the interpreting policy should be in an international gathering of deaf people – the natural sign language of the location of the gathering or an international variety or both (Rathmann *et al*., 2000). These are all issues that are the subject of debate in many deaf communities around the world.

Discourse Analysis

As with spoken languages, the discourse of natural sign languages is structured and subject to sociolinguistic description (Metzger and Bahan, 2001). Signers use natural sign languages and choices between natural sign languages and other kinds of signing to make statements about who they are, what their group loyalties are, how they perceive their relationship to their interlocutors, and what kind of speech event they consider themselves to be involved in. Sign languages are used to establish or reinforce social relations and to control the behavior of others. Sign language discourse has internal structure and is governed by norms such as how many people sign at once, how much one person should sign, what can be signed about in public, how a conversation should be entered or left, how turns should be allocated, how repairs should be undertaken, and so forth. Topic and the world knowledge that individuals bring to the discourse may also structure it (Roy, 1989), and sign language discourse can be described in terms of register variation (Lawson, 1981; Deuchar, 1984; Zimmer, 1989). The concept of 'language as skilled work' is applicable to sign languages, as skill is demonstrated both in everyday use of language and in special forms such as storytelling and poetry (Winston, 1999).

Sign Languages of the World

The Current State of Knowledge

After more than 30 years of systematic sign language research, most sign languages throughout the world still remain scarcely documented or even entirely unknown. We can only estimate how many sign languages exist in the world, and we are even less sure about how they may be grouped into language families. A few sign languages in industrialized countries are reasonably well documented, whereas little is known about sign languages in other areas of the world, such as sub-Saharan Africa, Southeast Asia, and the Arab world. Nevertheless, increasingly more information has been coming to light during the past decade, although we are still far away from systematic linguistic documentation in most cases.

Based on what we know to date, it is fairly clear that the sign languages of the world number in the hundreds rather than in the thousands and are thus much fewer in number than their spoken counterparts. For all we know, they are also much younger than spoken languages, although other forms of gestural communication are as old as humanity itself. The latest edition of the *Ethnologue* (Grimes, 2004) lists approximately 100 living sign languages. However, there are many omissions and errors in this list, so the actual number of sign languages in the world is likely to be at least three or four times greater.

The maximum documented age for a sign language is slightly more than 500 years for the sign language used at the Ottoman court in Turkey (Miles, 2000). There is no reason why the large cities of antiquity

Sign Languages of the World

The Current State of Knowledge

After more than 30 years of systematic sign language research, most sign languages throughout the world still remain scarcely documented or even entirely unknown. We can only estimate how many sign languages exist in the world, and we are even less sure about how they may be grouped into language families. A few sign languages in industrialized countries are reasonably well documented, whereas little is known about sign languages in other areas of the world, such as sub-Saharan Africa, Southeast Asia, and the Arab world. Nevertheless, increasingly more information has been coming to light during the past decade, although we are still far away from systematic linguistic documentation in most cases.

Based on what we know to date, it is fairly clear that the sign languages of the world number in the hundreds rather than in the thousands and are thus much fewer in number than their spoken counterparts. For all we know, they are also much younger than spoken languages, although other forms of gestural communication are as old as humanity itself. The latest edition of the *Ethnologue* (Grimes, 2004) lists approximately 100 living sign languages. However, there are many omissions and errors in this list, so the actual number of sign languages in the world is likely to be at least three or four times greater.

The maximum documented age for a sign language is slightly more than 500 years for the sign language used at the Ottoman court in Turkey (Miles, 2000). There is no reason why the large cities of antiquity

more than 2000 years ago should not have had groups of sign language users, but we do not have any reliable sources for these times. On the other hand, it is quite unlikely that communities of sign language users as we know them today would have existed even earlier. Only after urbanization had created reasonably large populations could critical numbers of deaf people theoretically have come together to use a sign language.

For many known sign languages, there is more or less detailed anecdotal evidence of historical links with other sign languages. These links may have to do with colonial history, migration of populations, or, in more recent times, the establishment of deaf education with the help of another country. The principal difficulty lies in determining whether a particular relationship between sign languages is genetic in nature (i.e., in how far we can speak of a sign language family) or whether we are dealing with a language contact situation. Attempts at addressing this issue have been largely unsuccessful, and no theoretically sound method of investigating historical relationships between sign languages is available.

In recent years, increasingly more sign languages are beginning to be documented. A first step is usually the compilation of basic vocabulary in word lists (pairing a word and a picture of a sign), which are often wrongly called 'dictionaries' (see Figure 1). During the past decade, these and other developments have resulted in a situation in which it is now possible to systematically compare linguistic structures across a much wider range of sign languages than in the past. The newly emerging field of sign language typology is concerned with the issue of how to systematize this new knowledge in a theory of variation across sign languages.

Sociocultural and Sociolinguistic Variables

Signed communication occurs in a variety of situations. This article is concerned exclusively with natural full-fledged sign languages that are the primary languages of their users. We are not concerned with artificially created sign systems such as 'Manually Coded English,' 'Signed Japanese,' and 'Dutch in Signs,' which have been invented for educational purposes with the aim of mirroring spoken language structures 'on the hands' (*see* **Sign Language: Communities and Cultures**). We are also not concerned with secondary sign languages that are used in communities where the usual mode of communication is through a spoken language but where signed communication plays a supplementary role for certain purposes, such as conditions of speech taboo. Rather, the sign languages we are interested in involve groups of deaf people for whom the sign language is the primary means of communication.

The first sign languages that were documented in detail from the 1970s onwards are used by communities of deaf people in urban settings. These are minority languages in which most of the users are deaf and there is constant language contact with the surrounding spoken/written language of the majority culture of hearing people. This situation is well described and occurs in urban areas in all regions of the world.

However, sign languages also exist in an entirely different sociocultural setting that is less well documented but highly significant for cross-linguistic comparison. These sign languages are used in village communities with a high incidence of hereditary deafness. Village-based sign languages arise because deaf individuals have been born into the village community over several generations, and therefore a sign language has evolved that is restricted to the particular village or group of villages. These sign languages are typically used by the whole village population no matter whether deaf or hearing, and in this sense, they are not minority languages, nor do they face any linguistic oppression. They have developed in isolation from other sign languages and are not used in any educational or official context. Deaf people are fully integrated into village life and may not be considered to be 'disabled' in any sense (Branson *et al.*, 1999). The existence of village-based sign languages has been reported from places as diverse as Bali, Ghana, Thailand, Mexico, an Arab Bedouin tribe in Israel, and a native Indian tribe in the Amazon, but their linguistic documentation is only just beginning. These languages have the potential to call into question many of the general assumptions that were made previously about the structure of sign languages.

Some village-based sign languages are already endangered and have not been documented in detail. As the larger, urban sign languages move in through formal education and the media, these small, locally restricted sign languages face similar pressures as their spoken language counterparts (*see* **Endangered Languages**). Similarly, sign languages in some developing countries have been under pressure from foreign sign languages, as in many African countries. In places where the deaf community is very large and the indigenous sign language has had time to develop on its own, it is relatively immune to foreign influences, as is the case in China and in the Indian subcontinent.

Despite similarities with respect to language endangerment, the life cycle of sign languages also differs from that of spoken languages in that new sign languages continuously emerge throughout the world, as most famously documented in Nicaragua (Kegl

et al., 1999). Throughout the world, urbanization and the spread of special education for the deaf create new deaf communities with newly emerging sign languages. The stage of a sign language's life cycle is an important consideration for comparing the structures of sign languages.

Relationships between Sign Languages

For a number of individual sign languages as well as groups of sign languages, the notion of sign language family has been proposed, based on known facts about their relationship with each other. For example, it is well-known that sign language was brought to New Zealand and Australia from the United Kingdom, and therefore these three sign languages make up the 'British Sign Language family.' For different historical reasons, the Japanese Sign Language family includes sign languages in Taiwan and Korea, both of which had been under Japanese occupation. In cases in which one and the same sign language-using community seems to have split and subsequently developed independently from each other, the traditional family tree model can be applied, and the shared history is visible and interpretable. Sign languages in Australia, New Zealand, and the United Kingdom are still mutually intelligible to a large extent and share most of their vocabulary, to the extent that it is doubtful whether they should not be classified as dialects of one and the same language. Sign languages in Korea, Japan, and Taiwan all share a peculiar grammatical mechanism of gender marking, with the thumb indicating male and the little finger female gender as formative elements in complex signs (see Figure 2). This feature is not found in any other known sign language and, together with other factors, makes a strong case for positing a shared history of this sign language family.

However, the situation is usually not so clear-cut. In most cases, it is impossible to determine whether similarities between two sign languages are the result of a genetic relationship or the result of language contact. Instead of the 'pure' kind of family tree relationship, a more common type of relationship between two sign languages involves various kinds of language contact situations, language mixing, and creolization. For example, American Sign Language is said to have arisen in a creolization process, where Old French Sign Language came in contact with indigenous sign varieties, resulting in a new language with input from both of these sources. This kind of relationship cannot be considered genetic in the usual sense of the term.

In many cases, there is more or less clear historical evidence of relationships between sign languages. This may be related to colonial history so that, for instance, sign language communities in the Indian subcontinent use a two-handed manual alphabet as in British Sign Language. However, actual historical documentation of how this came to be the case is lacking, there are very few meaningful similarities in the vocabulary and grammar of the two sign languages, and there is thus no evidence for including Indo-Pakistani Sign Language in the British Sign Language family. Another common factor in linking two sign languages often involves the establishment of educational facilities for the deaf. For instance, the sign language in Brazil is said to have its root in French Sign Language because a deaf Frenchman established the first school for the deaf in Brazil, and Swedish Sign Language was similarly brought to Finland. We find this kind of link between many African countries and one or more Western 'source' sign languages (Schmaling, 2001). American Sign Language (ASL) has had a major impact on deaf communities in other countries, such as Thailand, the Philippines, Uganda, Zambia, Ghana, Malaysia, and Singapore, and it is often unclear whether the sign languages used in these countries should be considered dialects of ASL, descendants of ASL in a family tree of

Figure 2 Gender marking in South Korean Sign Language: SCOLD(someone), SCOLD(me), SCOLD(a male person), SCOLD(a female person).

languages, ASL-based creoles, or independent sign languages with extensive lexical borrowing from ASL. To the extent that indigenous sign languages already existed in these countries and secondarily came under the influence of a foreign sign language, the relationships between them are not genetic in the usual sense but are instances of language contact.

This kind of problem is not unknown for spoken languages but is aggravated by a number of complicating factors in the case of sign languages. First, the familiar historical–comparative method that is used to determine language families and reconstruct older forms of source languages has never been applied to sign languages. No process of regular sound change has been identified, and the comparison of morphological paradigms is often compromised because the forms in question are iconically motivated. Vocabulary comparisons are highly unreliable, and there seems to be a considerable 'baseline level' of iconically determined lexical similarity even between unrelated sign languages (Guerra Currie *et al*., 2002). The first family trees that were proposed for sign languages were based on historical evidence and lexical similarities, and later attempts at using glottochronology on the basis of word list comparisons (Woodward, 1993, 2000) are similarly unreliable.

Another complicating factor in many cases is the uncertainty about whether or not there were indigenous sign varieties before the influence of a foreign sign language set in and, if so, what the linguistic status of this signed communication might have been. It is possible that in a particular region, limited home sign systems came in contact with a foreign full-fledged sign language, resulting in a new sign language in a process that has no counterpart among spoken languages. Finally, the lack of any historical records makes it difficult to directly test and evaluate any proposed historical relationship between sign languages. In the absence of any sound methodology for establishing sign language families, the issue of how one sign language is related to another one usually remains unresolved.

Grammatical Similarities and Differences across Sign Languages

Over time, sign language linguists have come to expect certain features in the structure of sign languages that have been shown to occur with great regularity in most or all sign languages known and described so far. Accordingly, there are attempts at accounting for these putative sign language universals on the basis of their visual–gestural modality. For instance, sign languages offer the possibility of using spatial grammatical mechanisms by virtue of being three-dimensional languages, and therefore they tend to use movement modifications to express aspectual distinctions or to use movement direction to code verb agreement (*see* **Sign Language: Interpreting**). Since the articulators in sign language are larger and slower than in a spoken language, sign languages tend to mark grammatical functions in a simultaneous rather than a sequential fashion; therefore, they use nonmanual behaviors such as facial expressions to mark sentence types (questions, negation, and subordination), and they use complex signs with numeral incorporation (e.g., a single complex sign meaning 'three months') (*see* **Sign Language: Morphology**). It has been claimed that sign languages are similar in the kinds of complex simultaneous morphology just mentioned but differ from each other in sequential morphology such as clitics and affixes, with sequential morphology being comparatively rare in sign languages (Aronoff *et al*., 2000).

Most of these generalizations about the similarities between sign languages are based on investigations of a limited number of languages, mainly in Europe and North America. The picture changes somewhat when examining a larger range of the world's sign languages. Although the previous observations are indeed true of many sign languages throughout the world, this is only part of the story. First, some sign languages do not show the 'expected' types of structures. Two unrelated village-based sign languages, in Bali and Israel, do not show an elaborate system of spatial verb agreement as is familiar from other sign languages. Another village-based sign language in Ghana does have spatial verb agreement but does not use the so-called 'classifier' hand shapes to refer to categories of moving persons, animals, and vehicles (*see* **Sign Language: Syntax**). Given that village-based sign languages have developed in isolation from any other sign language and exist under very different sociolinguistic conditions, it is not unexpected to find important differences in their structures in comparison with urban sign languages.

The range of possible structures in sign languages expands considerably when we consider non-Western, lesser-known sign languages. The gender marking system in the Japanese Sign Language family represents one such example. Sign language varieties in China also show many particularities that are not familiar from documented Western sign languages. Chinese Sign Language varieties include so-called 'character signs,' a particular type of borrowing in which the shapes and movements of the hands imitate the whole or part of words from the Chinese writing system (see **Figure 3**). Both northern and southern sign language varieties in China also make use of a productive mechanism of negation in which negative

Figure 3 Character signs in Chinese Sign Language.

Figure 4 Chinese Sign Language signs with ''little finger'' negative morpheme: DEAF and TASTELESS.

signs are marked by an extended little finger and the positive counterparts have an extended thumb (see Figure 4). Finally, question words for quantifiable concepts include one or two open hands with finger wiggling as part of complex signs, forming a large paradigm of interrogatives. The study of a greater range of sign languages thus reveals a large number of previously undocumented grammatical structures, just as the study of 'exotic' spoken languages did in earlier stages of spoken language linguistics.

Other structural differences between sign languages are more subtle and only come to light after systematic investigation. Typologically oriented studies across sign languages exist for a limited number of grammatical domains (for pronouns, see McBurney, 2002; for questions and negation, see Zeshan, 2004a, 2004b). Such studies show that the degree of structural differences between sign languages may be considerable but is unevenly distributed across different parameters of investigation. For example, sign languages differ as radically as spoken languages with respect to the set of their possible question words. A sign language may have only a single question word, as in certain dialects of Indo-Pakistani Sign Language (see Figure 5), or more than a dozen, as in Hong Kong Sign Language. On the other hand, the facial expressions accompanying questions tend to be very similar across unrelated sign languages, with eye contact, forward head position, and eyebrow movement as prominent features. Understanding the reasons for these patterns is important for building a theory of typological variation across sign languages.

Another important result from comparative studies is that certain sign language forms may look very similar superficially but in fact have very different properties. For instance, in a broad range of 38 sign languages throughout the world (see Figure 6), it has been found that in each case, negation can be expressed by a side-to-side headshake (Zeshan, 2004a). However, the grammatical constraints governing the use of headshake negation in fact differ greatly across sign languages. Whereas in some sign languages, such as in the Scandinavian region, headshake negation is a primary negation strategy and may often be the only instance of negation in the clause (Bergman, 1995), other sign languages, such as in Japan and Turkey, obligatorily use a manual negative sign with or without headshake negation as a secondary accompaniment. Sign languages in the eastern Mediterranean region (Greece, Turkey, and neighboring Arab countries) additionally use a single backward head tilt for negation that has not been found in any other region of the world (Zeshan, 2002).

It can be assumed that the significance of many possible parameters of variation across sign languages has not been recognized. For example, mouth movements deriving from a silent representation of spoken words, so-called 'mouthing,' carry an important functional load in some sign languages (e.g., in Germany, The Netherlands, and Israel) but are functionally largely irrelevant in Indo-Pakistani Sign Language (Boyes Braem and Sutton-Spence, 2001). The presence or absence of contact with literacy may be another important factor, evidenced by the fact that not all sign languages use an indigenous manual alphabet for fingerspelling (*see* **Fingerspelling**).

Future Developments

The dynamics of developments throughout the world with respect to sign languages and their

Figure 5 Combinations with the Indo-Pakistani Sign Language question word (WH): PLACE+WH ''where'', TIME+WH ''when''.

Figure 6 Sign languages represented in the typological survey on questions and negation.

documentation carry considerable momentum. Some sign languages are endangered, whereas others are expanding in geographical spread and contexts of use, and some are only just being created by new communities of users. Forces such as intensive contact between sign language and spoken language, as well as between one sign language and another, and the move toward official recognition for sign languages and the deaf communities that use them rapidly change and reshape the makeup of many sign languages worldwide. It is a continuous challenge for sign language linguistics to keep up with these developments and put together an increasingly detailed picture of linguistic diversity among the world's sign languages.

Sign Theory and Semiotics/Sign Theory vs. Semiotics

Semiotics, if taken as a scientific, theoretical, and philosophical approach as a whole, is more often than not considered synonymous with the terms 'theory of signs' or 'sign theory.' In this view, treating 'sign theories' would be equal to treating semiotics as a very comprehensive intellectual endeavor and indeed age-old human 'project,' and would thus be in the present framework tautological with an entry on 'semiotics.' What will be discussed here are the theories about the fundamental unit of sign systems and processes: 'sign theories' in the closer sense, theories about the sign itself as the central topic of theoretical semiotics. Such theories may in some cases comprise not much more than explanations; in major cases, they comprise theoretical consequences such as sign typologies or conceptions about sign functions. 'Theory' may also tendentiously coincide with 'model,' 'conception' or 'definition.' In this view, one accepts that semiotics is an 'overarching metadiscipline' (Stam *et al.*, 1992: 1) comprising (besides sign theories) theories of sign systems and processes, text theories, discourse theories, theories of narration, theories of sign 'dimensions,' code theories, and even media theories, etc. Also included are the 'doctrine of signs,' what is not the same as 'theory' (as the late Thomas A. Sebeok, spiritus rector of the semiotic community, never got tired to hint at), and even entire theories of culture, as in the semiotics of

Sign Theory and Semiotics/Sign Theory vs. Semiotics

Semiotics, if taken as a scientific, theoretical, and philosophical approach as a whole, is more often than not considered synonymous with the terms 'theory of signs' or 'sign theory.' In this view, treating 'sign theories' would be equal to treating semiotics as a very comprehensive intellectual endeavor and indeed age-old human 'project,' and would thus be in the present framework tautological with an entry on 'semiotics.' What will be discussed here are the theories about the fundamental unit of sign systems and processes: 'sign theories' in the closer sense, theories about the sign itself as the central topic of theoretical semiotics. Such theories may in some cases comprise not much more than explanations; in major cases, they comprise theoretical consequences such as sign typologies or conceptions about sign functions. 'Theory' may also tendentiously coincide with 'model,' 'conception' or 'definition.' In this view, one accepts that semiotics is an 'overarching metadiscipline' (Stam *et al.*, 1992: 1) comprising (besides sign theories) theories of sign systems and processes, text theories, discourse theories, theories of narration, theories of sign 'dimensions,' code theories, and even media theories, etc. Also included are the 'doctrine of signs,' what is not the same as 'theory' (as the late Thomas A. Sebeok, spiritus rector of the semiotic community, never got tired to hint at), and even entire theories of culture, as in the semiotics of

culture, or of society at large, as in sociosemiotics, on the one hand, and the application of theories, on the other – in the broadest, rather sociological sense, the entire semiotic community itself, including its infrastructures, because there is no semiotics without semioticians and all their intellectual as well as practical tools.

Pretheoretical Sign Conceptions

The term 'sign' appears theoryless already in everyday language, for instance, in combinations like 'traffic signs' or 'star signs' (which are signs in scientific understanding but in a more complex way). If people (for instance, in Vienna, Austria) used to say that the bunch of conifer branches over the entrance of a certain type of wine tavern is a sign that this tavern is a '*Heurigen*' (a locality where one can consume the wine from last year together with certain popular food), then they mean by sign only that particular element, the bunch, which in different semiotic terminologies is called e.g., 'sign vehicle,' 'signans,' 'representamen,' or 'means,' that is, the visible carrier of this special meaning, *Heurigen*. Why the bunch carries meaning at all and needs further components to function (in this case, to indicate the tavern) is a matter of mere habit but not of theoretical reflection.

In this example, one can make out, or presuppose, an intuitive understanding that the bush 'stands for' something else, the tavern and all what is connected with it (also a social institution, i.e., the specific type of Viennese localities called *Heurigen*, quite different from pubs, restaurants, McDonalds, etc., because one finds the bunch over each individual '*Heurigen*'): *aliquid stat pro aliquo*, but this popular understanding of the term 'sign' would not cover, for instance, written or spoken words, a painting, a photograph, or a film sequence.

As a matter of fact, other sciences than semiotics (and sometimes linguistics and philosophy) use the term 'sign' too, but mostly also in an everyday language understanding, or in some diffuse ways nursed by *ad hoc* descriptions. The minimal prerequisite for describing a 'sign' systematically is what Roman Jakobson called *renvoi* 'referring back to,' and this definition is therefore the germ of a genuine sign theory, or a rudimentary scientific consideration of the sign phenomenon. A semiotic view on the sign is always dynamic-relational; it highlights the fact that by the term 'sign,' semioticians try to describe the interaction and/or mutual interdependence of the components involved in a sign process, that is, in semiosis, which is the final-instance term, while 'sign' is already a kind of analytical abstraction, in whichever current of semiotic thought.

Sign Theories and Conceptions in History

Leaving aside some seemingly semiotic terms like 'signal,' a term used in information theory, sometimes (ambiguously) in biology, and in certain situations in everyday language (an alarm clock 'signalizes' the sleeper to wake up), which in some uses can be made compatible with a semiotic understanding and in some not, the focus should now first be on the history of attempts to identify the elements of the sign. There exist several comparative overviews of sign conceptions since antiquity, for instance in Eco (1977b) and Nöth (1990: 88, 90). The latter's interest is to show that the fundamental controversy being also characteristic of the two mainstreams in modern semiotics; the differentiation into dyadic and triadic sign conceptions, can be already found in the theorizing about signs since antiquity, in Scholastic thought, in the Baroque era, in the Age of Enlightenment, in German idealist philosophy, and at other stages of the history of mind.

This list contains Nöth's synopsis of dyadic models of the sign (1990: 88) (here very selectively in parentheses: the notions for the sign; the notions for the two correlates):

- Augustine (sign; sign (as thing)/something else)
- Hobbes (sign; antecedent experience/consequent experience)
- Degérando (sign; sensation/idea)
- Cassirer (symbol(ic) form; concrete sensible sign/content, meaning)
- Bloomfield (linguistic form; speech sound, signal/response in hearer)
- Buyssens (seme; semic act/meaning, signification)
- Jakobson (*signum*; *signans*/*signatum*).

In the synopsis of triadic models (1990: 90), one finds e.g., the following authors (again selectively: same order but three correlates):

- Plato (name; sound/idea, content/thing)
- Stoics ((sign); *sémainon*/*sémainómenon*/object or event)
- Bacon ((word); word/notion/thing)
- Husserl (sign; expression/meaning/thing)
- Ogden and Richards (–; symbol/thought or reference/referent).

In both cases, these exemplary lists (thus also in Nöth, 1990, not aiming at completeness) span centuries and include some founding fathers of modern semiotics, who will be dealt with below, and some major figures of modern theorizing too. Nöth commented:

> A clear-cut distinction between dyadic and triadic sign models is not always possible [...]. There is a zone of vagueness whenever a third correlate is mentioned but

> not systematically incorporated into the semiotic theory (1990: 87).

And later on:

> Triadic sign models comprise a non-homogeneous group of semiotic theories distinguishing three correlates of the sign, sign vehicle, sense, and referent [. . .]. In some cases, there is no distinction between dyadic and triadic models (1990: 89).

These two comments show that, although there are clearly two distinctive trends throughout history, it also very much depended on the research frameworks, perspectives, and interests of the authors, and also on their individual cognitive disposition and *weltanschauung*, which components they emphasized. One can nonetheless recognize an implicit tendency towards a possible reconciliation of these two standard views or generalized conceptions, despite the fact that even still in the 1960s, 1970s, and 1980s of the 20th century (that is, in the era in which semiotics became a broader movement and a transdiscipline), the question whether dyadic or triadic evoked many vivid controversies.

Meanwhile, this article will risk here to characterize the current phase of the semiotic movement as its 'enyclopedic phase,' that is, with comprehensive metavolumes like Sebeok (1986: 3 vols), Bouissac (2000), and especially Posner, Robering, and Sebeok (1997–2004: 4 vols), while also Nöth's first edition of *Handbuch der Semiotik* (1985), indeed at the beginning an introduction, has grown in its last version (2000) to a remarkable kind of encyclopedia. Each of these works has its advantages but also some blind spots, so that it can only be recommended to use them in their complementarity. Anyway, by this and/or parallel with this development, the mentioned controversies have become less characteristic, are more or less outdated, and were replaced by the rise of a comparative semiotics, on the one hand, and an 'intersemiotics' (Gérard Deledalle's term), on the other, which even tries to elaborate the common grounds or the common smallest denominator of the different currents in semiotics, despite their roots in different traditions within the history of mind. This search for common ground means no unification but a tendency towards mutual complementarity or completion. Before shifting the discussion still dominating sign theories and some vitally coexisting ones of major importance, it seems necessary to give a very short assessment of the megatrends in recent semiotics.

Mainstreams and Currents in Modern Semiotics

In the first version of Nöth's *Handbuch* (1985), one can find an attempt at classifying the existing currents of modern semiotics of that time, which is a correct, although incomplete, report identifying far more than a dozen currents (1985: 4–9). In view of the present aims, it suffices however to refer to this enumeration, although some further groups have taken shape since then. There are a number of distinct currents such as (comments in parentheses): (1) semiology and general semiotics; i.e., the linguistic-structuralist respectively the Peirce–Morris paradigm; (2) a functionalist semiotics (Martinet, Mounin, Prieto; structuralist, too); (3) Marxist semiotics (could as well function as part of a comprehensive sociosemiotics: marxist, marxistoid, and nonmarxist, e.g., Alfred Schütz); (4) phenomenological semiotics (indeed one of the 'philosophical' subcurrents); (5) diverse 'schools', e.g., Prague School (structuralist), Moscow-Tartu-School (structuralist), Paris School (structuralist), Stuttgart School (Bense's, clearly Peircean), 'sociosemiotic structuralism' (i.e., W. A. Koch, departing from structuralism, more recently rather bioevolutionary), and an action-theoretic approach (Trabant; tending toward sociosemiotics); and (6) poststructural(ist) semiotics, especially Derrida's grammatology and Kristeva's *sémanalyse* (the first an 'extremist' structuralist, the latter a multiinfluenced boarderline case). It includes no biosemiotics at large, or no zoosemiotics, for instance.

In contradistinction, one could draft a more fundamental and therefore diminished typology based on the general points of departure. In this perspective, the two mainstreams have to be the same, i.e., a philosophy-derived semiotics, with Peirce and Morris as the founding fathers, and a linguistically inspired semiotics (departing from Saussure; structuralisms in any sense). Then one can identify two clearly 'deviating' wings: biosemiotics (departing from Jakob von Uexküll), and sociosemiotics (founding father: M. M. Bakhtin in his Vološinovian appearance; most elaborate version: Rossi-Landis). These are four qualitatively different currents since their immanent logic is entirely different: Peirce's comes from thought (inference), the structuralisms from Saussure's *langue* as the most advanced sign system, biogenetic biosemiotics from bio-logic, and sociogenetic sociosemiotics from socio-logic (thus, not to be confused with e.g., Greimas' *sociosémiotique*, a kind of substitute for pragmatics).

The different currents can be condensed to four plus a zone of interaction, i.e., intersemiotics. The major divide in the second half of the 20th century concerned the linguistics-derived structuralisms (including even poststructuralism; in this view, only a radical variant of the former), on the one hand, and the more philosophically motivated, or nursed, approaches, on the other (i.e., motivated by

pragmatism/pragmaticism plus related orientations, such as behaviorism, phenomenology, etc.). The foci of this divide are the respectively underlying sign theories or conceptions, in first approximation: dyadic vs. triadic. The rise of biosemiotics as well as sociosemiotics, the first already in a distinct shape, the second in a way not yet clearly depicted by the mentioned encyclopedias, but obvious after careful inspection, suggests that the future discussions in semiotics, as far as it concerns its foundations, will rather concentrate on the differences (as well as possible coincidences) between biosemiotics and sociosemiotics (or anthroposemiotics). And it is again the sign theories on which these currents are based that will play an important role in this interaction.

The Major Structuralist Sign Theories in Modern Semiotics

In this perspective, the major sign theories shall now be presented that are at the core of these different general orientations of semiotics at the turn of the millennium. The founding fathers of the structuralist approaches are, first of all, Saussure, who drafted what he called semiology, and Louis Hjelmslev, who, in his glossematics, developed an indeed comprehensive semiology/semiotics, although he foremost concentrated on verbal signs. (It is important to note that Saussure had a vision and showed a way how to follow it, but it was Peirce who developed the first comprehensive semiotics in the modern sense as well as a genuinely differentiated theory of the sign in the closer understanding).

Saussure's sign theory (1916/1986) can be pinpointed by his excessively quoted sign model, a lying oval, divided horizontally by a broken line (the 'bar'); in the upper half stands *signifié*, in the lower *signifiant*; one arrow on the left points upwards, another on the right downwards. This configuration tries to depict the structure of the linguistic sign, first of all in spoken language. The idea behind it is, that there are (in our minds) two distinct planes of mere form, the planes of thought and sound, from which the speakers arbitrarily draw small parts and correlate them. The correlate of a piece of plane 1 and of a piece of plane 2 is the material to shape the sign. In this sense, Saussure

> offered a two-part model of the sign [...which] he defined [...] as being composed of a 'signifier' (*signifiant*) and a 'signified' (*signifié*). Contemporary commentators tend to describe the signifier as the form that the sign takes and the signified as the concept to which it refers (Chandler, 2002: 18).

Sometimes, instead of the word *signifiant* appears the words *image acoustique*; instead of *signifié*, *concept*. For him, the (image of the) sound pattern and the concept were psychic phenomena: forms but not substance. For Saussure,

> the sign is the whole that results from the association of the signifier with the signified [...] The relationship [...] is referred to as 'signification,' and this is interpreted in the Saussurean diagram by the arrows (Chandler, 2002: 19).

Therefore, the quintessence is that Saussure's sign theory is a mentalistic one, and the relationship of the *signifiant* to external sign carriers remains undefined since it is not in the center of interest. The same goes for the relationship between the *signifié* and what is externally represented by it. This view is an understandable one of the rise of positivism in the humanities at Saussure's time. While he tried to isolate the smallest unit of language, the linguistic sign, the early sociologists tried to define the true topic of their young discipline, the social, by reduction. It would be one of the major problems of the later structuralisms that the sign 'remained' entirely in the heads of the speakers. Although the majority of indebted researchers maintained Saussure's understanding of the sign, some implicitly (e.g., members of the Moscow-Tartu School) and some explicitly (Roman Jakobson) rematerialized the *signifiant* for practical reasons.

To close this short presentation of the Saussurean sign conception, one should, however, remark that Saussure also made original efforts with lasting effect to theorize the connection between the signs semiotically (or rather semiologically). Central notions, as to this, are value and difference. The value of a sign depends on its position in a (sign) system, and the sign system 'language,' like other sign systems, is one of functional differences and, consequently, oppositions. Since he departed from the study and analysis of the linguistic sign, he also stressed the arbitrariness of the sign, although he didn't deny the existence of motivated signs. Later on, when the structuralist semioticians extended their research more and more into fields of nonverbal and composite sign systems, the restrictions of the underlying sign theory became increasingly obvious, and some theorists adapted terms from Peirce's sign typology, such as index and icon, for motivated signs (see below).

Louis Hjelmslev (1943/1961) was the one to develop Saussure's vision of a comprehensive theoretical semiotics/semiology. In linguistics, he ranks as a great historical figure only, since his system wasn't very influential due to its alleged abstractness, but his reputation in the semiotic community is great. Although his theory also considers 'nonlinguistic languages,' his focus was (like Saussure's) on *langue* and/

as the general principle of semiotic structure. Thus, his structural linguistics, or 'glossematics,' appears in all major semiotic reference works as a genuinely semiotic approach towards the totality of all sign systems. Based on the Saussurean conception of the planes of sounds and ideas, he specified and stratified Saussure's sign model, in which he replaced the signified/signifier dyad by one describing directly the interdependence correlation of two forms: expression–form (EF) and content-form (CF). Both draw from their respective material: expression-form from expression–substance (ES), which is an already semioticized segment of the otherwise amorphous matter of expression–purport (EP). The same circumstances are mirrored on the side of content-form: content-form draws from content–substance (CS), which is an already semioticized segment of the otherwise amorphous matter of content–purport (CP). However, the sign in the strict sense is built only by the expression-form/content-form dyad, both nursed by their substantial environs. Thus, the six parts work together this way:

(1) EP – ES > <u>EF <> CF</u> < CS – CP

Only the underlined couple represents the sign, because: "Following on from another of Saussure's maxims, the sole object of glossematics is the pure, nonsubstantial form" (Trabant, 1987: 94).

This model is the core of Hjelmslev's sign theory and allowed him to build an extensive semiotics in which he could very systematically thematize phenomena like – to quote one of the best known of his accomplishments – connotation, which he understood in a broader sense as

> something far more general, namely everything that the sign says about the speaker [...] as something that the sign says about itself [...E]very sign participates as a matter of principle in several connotative semiotic structures (Trabant, 1987: 100–101).

Besides the cited abstractness claimed by linguists and also some semioticians, such as Eco, (1977a: 41) who found his 'jargon impenetrable' and criticized the lack of examples from other sign systems than language, another fact also hindered the proliferation of his ideas: the deviating use of the term 'semiotics.' "Hjelmslev introduced the term *semiotic* for language in this broad sense [...T]he distinction between language and semiotic, and with it the distinction between linguistics and semiotics, tends to dissolve itself' (Nöth, 1990: 65–66). Instead, what is understood now by semiotics appears in Hjelmslev's theory as 'metasemiotics.' There is no doubt, however, that he contributed decisively to sign theory in the closer sense as well as to semiotics in general, and his influence on certain important movements in semiotics, most of all on the 'Paris School' around Greimas, cannot be overrated.

The Major Pragmat(ic)ist Sign Theories in Modern Semiotics

Charles S. Peirce is the next founding father of sign theory to be reviewed, and with him, we enter the field of triadic conceptions in the modern understanding. (Common in Peircean scholarship, quotes and citations will be identified by volume and paragraph number, such as 2.228, from Peirce [1931–1958].) Charles W. Morris (cf. esp. 1938, 1970) was a co-founding father of this current in the first half of the 20th century. A further prominent witness from the second half of the century, Max Bense (Bense and Walther, 1973), developed on mainly Peircean foundations his so-called basis theory, a theory tending to formalize Peirce's thought by mathematical means. Although Peirce himself never used an equilateral triangle △ to diagrammatize his sign model, one could take the Bensean triangle as a tool for roughly modeling his conception as well as the ones developed by Peirce and Morris (despite some remarkable differences), all in one.

In this sense, in the left corner of the triangle one could place

- in Peirce's case: object
- in Morris' case: designatum/denotatum
- in Bense's case: object.

In the right corner:

- Peirce: interpretant
- Morris: interpretant
- Bense: interpretant.

In the upper corner:

- Peirce: sign or representamen
- Morris: sign vehicle
- Bense: sign or means (German: *Mittel*).

The triangle stands for triad and triadic conception, by which is meant, that all three parts must coexist since they condition each other, as there is no child without father and mother, no mother without father and child, etc. Translated into a definition, Peirce's understanding of the sign, which is rooted in his most general philosophical idea, his theory of categories (Firstness, Secondness, Thirdness), is as follows:

> A sign, or *representamen*, is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign [...]. That sign which it creates

> I call the *interpretant* of the first sign. The sign stands for something, its *object* [...] not in all respects, but in reference to a sort of idea (2.228).

It has to be noted that Peirce, who dealt with the sign problem all his life and approached it at different times and from different angles, has left us several dozens of definitions and analytical descriptions of the sign. Marty (1990) has shown by mathematical means, however, that he always indicated the same with different words. Peirce's sign theory may thus be considered as a steadily scrutinized and validated construct that indeed meets the point. In the above formulation, representamen is his term for the conveyable material substrate, the object is what the sign represents, the interpretant the meaning of the sign and at the same time, another sign – the root of the idea of the possible endless concatenation of signs, of unlimited semiosis.

Peirce distinguished further between an immediate and a dynamical object on the one hand, and an immediate, a dynamical, and a final interpretant on the other. By this, he tries to describe a kind of corridor, or continuity, between inside and outside (the sign as well as the sign user). The final interpretant is a 'habit' by which the endless sign chain is made to come to a provisional end. Conceptually very important is Peirce's sign typology, because it is the only one directly derived from the sign model, and it became (in parts) influential within other semiotic approaches. Sign typologies are not exactly the topic of this presentation, because most are empirically conceived. However, his is a constitutive part of the sign theory, thus it must be mentioned here. From the representamen relation derives a trichotomy built of qualisign, sinsign (token), and legisign (type); from the interpretant relation, one of rhema, dicent, and argument (generalizing the old division of term, proposition, and argument in logic). The most influential trichotomy (also outside traditions indebted to Peirce) became the one concerning the object relation: icon, index, and symbol (the first two motivated, either by similarity or contiguity, the latter arbitrary); the icon renders moreover a subtrichotomy of image, diagram, and metaphor. From the nine terms of the main trichotomies, Peirce built his highly systematic and differential tool for sign classification, which comprises 10 sign classes (Bense's 'basis theory' follows him in all major respects, see below, as does the greatest part of the closer Peirce community within semiotics).

Morris' triadic sign model consists of the three components designatum/denotatum (D), sign vehicle (S), and interpretant (I; but he stressed also the importance of the interpreter and the context). One of his definitions (although he emphasized not to define but to clarify the conditions of the possibility of signs) said: "*S* is a sign of *D* for *I* to the degree that *I* takes account of *D* in virtue of the presence of *S*" (Morris, 1938: 4), while D might be a denotatum (a real object referred to) or a designatum (a class of items). This formula is used not only for human signs, but also for any kind of organisms. Morris intended a biologically and behavioristically based science, including the study of what could be called protosemiosis, or animal sign use. The interpretant is a reaction upon the sign in an organism.

Thus, influenced mainly by Peirce and by G. H. Mead's social behaviorism, Morris developed a sign theory uniting, in the final analysis, the philosophical traditions of rationalism (as to the syntactic dimension of semiosis), empiricism (as to the semantic dimension), and pragmatism (as to the pragmatic dimension). From these three dimensions follow the three subdisciplines of semiotics, i.e., syntactics (concerning the relations between the signs themselves), semantics (concerning the significative relations), and pragmatics (concerning the relations between sign and sign user), terms that are to be understood in a broader form than found in linguistics. His research interests also included the dimensions of sign use, and of value in general, which led him to develop a semiotically based discourse typology (while his sign-typological suggestions were later on replaced by those within the Peirce reception).

Max Bense was the one to introduce Peircean semiotics in Europe, especially Germany, by initiating an international scientific community called school of scientific semiotics, or Stuttgart school. The core of his own 'basis theory' (first of all indebted to Peirce, but drawing also from Morris) is a trirelational sign model formulated as a triangular diagram with the three relata O, M, and I. The sign relation is defined as sign S = R(O, M, I), wherein the three relata are object, means, and interpretant. To stress the integrative role of the interpretant, also the formulation S = R((O, M)I) exists. The term *Mittel* 'means' has two meanings in German. First, it means tool or instrument. Secondly, in a more indirect way, it connotes also the thing in between, the mediating instance between the object and the interpretant. In Peirce as well as in Bense, there is a certain ambiguity concerning the seeming identity between sign and representamen on the one hand, and sign and means on the other. This ambiguity can easily be solved by recalling the fact that what is described componentially is a process, semiosis. The sign unfolds only in its actualization: the everyday language's sign equals sign vehicle and differentiates itself in its processually developing relata, among them representamen/means. Bense became famous by his

endeavor to develop a kind of notation, or formalization, based on cardinal numbers, that allowed him to denote Peirce's sign typology very systematically. Bense and his group delivered many applications to concrete sign phenomena, and he also offered some original theoretical contributions, such as his theory of reality thematization.

Sign Theories in Biosemiotics and Sociosemiotics

Next, let's turn to biosemiotics. From some remarks about Morris, it has already become clear that sign theories are not restricted to human sign use but may also concern the means of animal communication. Peirce knew about this view, as is quite obvious in a theory characterized (positively or critically) as pansemioti(ci)sm. The rediscovery of Jakob von Uexküll from the side of the semiotic community led to installing him posthumously as one of the founding fathers of modern semiotics (von Uexküll, 1983). Jakob von Uexküll, whose work developed in the first half of the 20th century, was a zoologist, biologist, behavior researcher, and most of all an *Umwelt* theorist, because his environment theory is the best known of his accomplishments. What is less recognized outside semiotic circles is that within his *Umwelt* theory, he also developed a sign theory that is crucial for the whole approach as such. For him, all this was simply 'biology,' but the present focus is a semiotic one, since the

> *objective* of *Umwelt*-research is to develop a theory of nature's composition, or to reconstruct the score to the 'symphony of meanings' that nature composes out of the innumerable surrounding-worlds (*Umwelten*)

wrote his son Thure von Uexküll, 1983: 149, who 'translated' his father's metaphors into modern more system-conscious language. A symphony of meanings must indeed rest on those elements that carry and convey meanings, i.e., signs. The central model of *Umwelt* theory is the so-called functional circle showing the ecological niche of an organism, i.e., the interaction between an individual organism's exchange with its *Umwelt* (or segment of *Umwelt*). On the subject's side, the organism has perceptual and operational organs to either experience the *Umwelt* object(s) or to (re)influence them, while the object(s) seen as a connecting structure possess perceptual and operational cue carriers. In between subject and object unfold the perceptual and the operational worlds. Subject (meaning utilizer) and object (meaning carrier) are linked in a whole, a sign (system). Actually, the *Umwelt* is the representation of the environment in the organism. In the functional circle's perceptual and operational worlds, already appear what von Uexküll called *Merkzeichen* and *Wirkzeichen*, and he also identified some other types of signs, but one can see the whole relationship as a sign process (semiosis), whose components can be identified:

> In the simple formula of sign = meaning carrier + meaning and meaning = reference to the meaning utilizer, 'meaning' has the central function of bracketing heterogeneous elements into a whole (the sign) [. . .]. Thus, the formula, meaning = link between carrier and utilizer, takes on the nature of a dynamic process (von Uexküll, 1987: 169).

As mentioned in the beginning, the scientific understanding of 'sign' is dynamic-relational, thus von Uexküell's view fulfills this condition. This theory has the enormous consequence that semiotics, mainly stemming from linguistics and philosophy, extends its relevance from culture to nature-and-culture.

It was Thomas A. Sebeok's (for an overview, see Baer, 1987; Bernard, 1997) major aim to deepen as well as to propagate this understanding of semiosis as well as semiotics; his point of departure was biology, thus he was an admirer of von Uexküll (although, concerning the mainstream protagonists, Sebeok also belonged to the Peirce-Morris line). He contributed to this expanded semiotics by developing biosemiotics, especially zoosemiotics. He hinted at the fact that there are myriads of sign systems outside the human species waiting for research; he steadily recalled also the medicinical roots of semiotics since antiquity; and he added moreover, the division between endosemiotics and exosemiotics, the first covering semioses taking place in an organism, the second covering semioses involving organisms and their *Umwelt*s. In his considerations about anthroposemiotics and zoosemiotics, he stressed the fact that many human sign phenomena belong to bio- and zoosemiotics at the same time. Concerning sign theory, he contributed only some additional suggestions, such as a sign typology especially useful for biosemiotics (signals, symptoms/syndromes, icons, indices, symbols, names), but his influence to push the whole semiotic community into a more 'global semiotics' was indeed great.

Concerning the sociosemiotic current (consciously written in hyphenated form, to distinguish it from narrower understandings of sociosemiotics without a hyphen, such as in Nöth (2000: 537) where only a kind of miscellanea semiotics appears) there is, despite some nearly unknown forerunners, also a true founding father, Mikhail M. Bakhtin (esp. Vološinov, 1929) who was the first major critic of Saussure. While the latter privileged *langue* as a system, Bakhtin emphasized *parole*, i.e., actualized, living, interactive language as the field proper of semiotic study, and

thus arrived at his famous principle of dialogicity. As to the term 'sign,' he seemed to use it in a sense similar to Saussure's, but he emphasized the closeness of sign and ideology, contrary to Saussure. However, one can reconstruct Bakhtin's more complex understanding of (the components of linguistic) semiosis, as it shall be suggested here: in an archetypical way, we could postulate that semiotics is about means of communication M, reference and/or reality R, senders S and percipients P in a more personal sense. We project 'dialogue' as the central agent into this diamonds-shaped form ◇. On the side of M, there is sign as structure and ideology as superstructure; on the side of R, first the theme, and then (social) reality; all encircled by the context, while two two-sided arrows point to and from the direction of P and S, symbolizing enduring interactivity.

It is widely accepted that Bakhtin, with these ideas, has been one of the precursors of sociolinguistics, and that with his later works, he has made important early contributions to what was called semiotics of culture in the 1960s, but his outstanding place in the ancestry of sociosemiotics has still to be more clearly established. It suffices for now to state, that there is a series of major authors building this current, such as Vygotskij, Lukács (in his sign–theoretic chapters), Schaff, Klaus, Resnikov, Schütz, Halliday, some Symbolic Interactionists, Robert Lafont, and many others, all of whom have in common that they stress the role of the sociality of human sign use, the relation and interdependence of signs and sign users, and the role of Man as a sign producer and receiver (re-producer).

The most elaborate theory of that sort is Ferruccio Rossi-Landi's (for an overview, see Bernard and Withalm, 1986). In his early phase, i.e., in the mid-20th century, he was the first to introduce Morris' semiotics to Europe. His declared aim was to extend Morris behaviorism to social(ized) behavior. He then criticized Saussure and the structuralist models by developing his own counter–concept of common speech (*parlare commune*, cutting across the Saussurean dichotomies), which later on, he extended to common semiosis. In the background appeared his concept of sign work, based on work as such as an anthropological constant. Work is defined as an endeavor that needs *sine qua non* a worker W, instruments I, materials M, an aim A, and (working) operations O, to render a product P; in the most condensed version (i.e., some factors already presupposed), a transformation triad M/O/P can be formulated. For sign work, it is principally the same. This conception is the basis (or 'hidden structure') underlying his most famous theoretical construct, the so-called Homology of Material and Linguistic Production (to be extended also to sign systems in general).

Less known but equally important is his unique sign theory condensed in the following sign model: a *signans* is the identifier of a piece ('coagulation') of society, the *signatum*. Both are melted together (for a while) to a sign (*signum*) as social result. But how does it happen that this transformation triad gets in motion? Because it is indispensably connected with the sign work triad M/O/P (wherein M is *signans* plus *signatum*, O the operations of the sign worker, and P the product, i.e., *signum*). (A three-dimensional diagram would be necessary to illustrate the interaction of the two triads, one at the level of semiosis, the other of sign work). An important part of Rossi-Landi's sign theory is his Theory of Sign Residues, which deals with the elements that enter or leave the signs on the side of *signans* as well as *signatum*. In his later works, Rossi-Landi concentrated on the theoretical embedding of the sign systems and processes in social reproduction, delivering finally a threefold model of society driven by three great triadic movements: material production; intermediary production, first of all sign production; and ideological production. The central locus or agent keeping the entire system together is the one of sign exchange equals communication. It is interesting to see that the summarized movement of all triads mentioned (the triad of social reproduction in general – social practice; social reproduction in its instrumental/operational aspects; history) still mirrors the triad M/O/P, though on a grander scale. This mirroring hints at the astonishing consistency of Rossi-Landi's thought throughout the decades.

An Intersemiotic Contribution

The last two sections presented the main sign theories in the described four major currents of modern semiotics. At this point, we enter intersemiotics and present an example of sign–theoretic intersemiotics, which goes beyond mere comparative semiotics. Bernard and Withalm (1987) offered a three-dimensional sign model that is first of all indebted to Rossi-Landi (i.e., refers to one of his special variants called situational triads) but draws also from Resnikov, Schaff, and Bystřina, and on deliberations about the whole history of sign theories. Their model is based on sociosemiotics, but intends also reconciliation with the mainstream paradigms. It is shown here in a simplified form reached by reprojection into two dimensions (**Figure 1**).

It doesn't claim to be a sign model, but rather a sign components' situation model. It comprises and identifies a larger triad consisting of *Signatum* Sm, *Signans* Ss, and *Signum* S (all with capital S; terminology like Rossi-Landi's above) that represents

Figure 1 Sign components' situation model.

the communicable external sign triad (wherein Sm is a socialized fact with intersubjectively accepted meaning), and driven (partly) by external sign work (P; M/I; while O presupposed), and a smaller triad inscribed (which depicts, in a way, Bystřina's 'model of the sign' or Peirce's 'thought sign'): the internal *signatum* sm, *signans* ss, and *signum* s, once again driven by sign work, this time a purely internal one (p; m/i; while o presupposed); A_{ZP} is the sign worker (in German: *Arbeiter als Zeichenproduzent*). If one is willing to accept the unified Peirce/Morris/Bense triad from above in first approximation as a triadic sign model as such, characterizing this mainstream, then an identification with Sm/Ss/S (with the interpretant as a Morrisian reaction in an organism presupposed) becomes possible; if one is willing to accept a more dialectical (and also more materialist) view on Saussure's mentalistic sign model and reads it as signified and signifier melted together by some brainwork to a complete internal sign, then an identification with sm/ss/s becomes possible. (One could also recognize that some rematerializations of the signifier in the history of structuralist semiotics would lead to sm/Ss/s, that is, would show that something is missing.) A biosemiotic sign model is admittedly not yet included and would be also questionable; reconciliation is suggested by means of comparison: what is common to human and animal *Umwelt*s, and what distinguishes them?

Special Cases: Sign Function Theories

A presentation of sign theories like the one in this article would be incomplete without a glance on the modeling of sign functions. In semiotics and other related sciences, the term 'function' usually refers to finality or to internal structural relationships within the subject matter; this reference touches the present topic only marginally. The matter is different, however, when it concerns a sign conception itself, what is sometimes the case especially with the pragmatic functions, that is, when the sign model as such thematizes sign functions. The best known and dominant tradition, as to that, is the one in the wake of Bühler, who proposed the so-called organon model, in which the sign has with regard to the sender an expressive function, with regard to the receiver an appellative one, and with regard to what is referred to, i.e., objects or states of affairs, a representative one. Based on Bühler, Jakobson's sign function model (1960: 353–357; originally developed for literary research reasons, but then generalized) is meanwhile to be found in nearly all introductions, scripts, glossaries, and textbooks on semiotics. It comprises six functions: an emotive function (as to the sender), a conative one (as to the receiver), a referential one (as to the context), a poetic one (as to the message itself), a phatic one (as to maintaining contact), and a metafunction (as to the code). An adaptation of Jakobson's model, to change with the times and include the ever increasing importance of the media, is Itamar Even-Zohar's (1990: 31) variant of the same model, which replaces the sender- and receiver-related terms by producer- and consumer-related ones, further context by institution, message by repertoire, contact by market, and code by product. Mukařovský's (1942/1977) pragmatic functions concern the sign just indirectly, rather the sign user and his/her self-realization vs. the world; they are of two kinds: immediate and mediated functions, the first divided into theoretical and practical ones, while the mediated ones are called semiotic functions.

Sign-Based Morphology

C O Orgun, University of California, Davis, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Sign-Based Morphology (SBM) is a theory of the phonology-morphology interface, proposed in Orgun (1996), that builds on unification-based syntactic theories such as G/HPSG (Gazdar *et al.*, 1985; Pollard and Sag, 1994) and Construction Grammar (Fillmore *et al.*, 1988), with which it shares the basic assumption that nodes in a constituent structure are signs – pairings of form (value of a PHON attribute) and meaning (value of a SYNSEM attribute). SBM aims to account for effects modeled in Lexical Phonology (Kiparsky, 1982; Mohanan, 1986) via interleaving, within a monotonic model of constituent structure building.

An SBM grammar consists of constructions, each of which is a description of an allowable configuration of a mother node and its daughter(s). Included in each construction is a specification of how the mother node's PHON and SYNSEM values relate to the daughter nodes' values. Each construction includes a function φ such that

$$\text{PHON}_{\text{mother}} = \varphi(\text{PHON}_{\text{daughter 1}}, \text{PHON}_{\text{daughter 2}}, \ldots)$$

Phonological strings (values of PHON) include segmental and metrical structure, but exclude other

'beat'	swallow-PASS.
	'be swallowed'

$$\begin{bmatrix} \text{PHON} & \text{[do:mu]} \\ \text{DAUGHTERS} & \left\{ \begin{bmatrix} \text{PHON} & \text{[do:m]} \\ \text{DAUGHTERS} & \{\text{[PHON [do:]], [PHON [m]]}\} \end{bmatrix}, \text{[PHON [u]]} \right\} \end{bmatrix}$$

Figure 1 Binary branching constituent structure (SYNSEM values suppressed for readability).

$$\begin{bmatrix} \text{PHON} & \text{[yenir]} \\ \text{DAUGHTERS} & \{\text{[PHON [ye]], [PHON [n]], [PHON [ir]]}\} \end{bmatrix}$$

Figure 2 Ternary branching constituent structure.

information such as morphological boundary symbols. Phonological sensitivity to morphological structure results from the chains of dependencies in the determination of the PHON attribute of a node through the application of the φ function of each intermediate node it dominates.

For example, consider a minimal size condition of two syllables that some Turkish speakers impose on suffixed forms (Itô and Hankamer; Inkelas and Orgun, 1998), as shown in Table 1. When further suffixation renders the forms disyllabic, we might expect them to be grammatical. This indeed works for *ye-n-ir* 'is eaten' but not for **do:-m-u* 'my (musical note) C, accusative'.

SBM handles this difference by assuming a binary branching structure for **do:-m-u* with each nonterminal node subject to the disyllabic minimal size condition, as shown in Figure 1. The intermediate node violates the minimal size condition; hence, the form is ungrammatical (forms are grammatical if and only if all their nodes are well-formed). By contrast, the form *ye-n-ir* is assumed to have a ternary branching structure, as shown in Figure 2. Because *ye-n* is not an intermediate form in this structure, there is no minimality violation. (Orgun, 1996, presents morphosyntactic data confirming the binary versus ternary branching contrast.)

Work in SBM has so far addressed cyclic versus noncyclic phonological effects, stratum ordering, morphologically conditioned phonology, paradigmatic versus structural accounts of phonology-morphology interaction, Bracket Erasure effects, and reduplication.

Significs: Theory

S Petrilli, University of Bari, Bari, Italy

© 2006 Elsevier Ltd. All rights reserved.

'Significs' is a term coined by Victoria Lady Welby (1837–1912, England) in 1896 for her theory of meaning and interpretation, which she developed in terms of the relation between sign, value, and behavior. Significs focuses on the sign's ultimate value and significance beyond semantic meaning and as such keeps account of the everyday expression, "What does it signify?" In contrast to such terms as 'semantics,' 'semasiology,' or 'semiotics,' 'significs' was free from technical associations. It follows that it was suitable to signal the axiological implications in the relation between sign and meaning, therefore the connection between sign and value in all its aspects – pragmatic, social, ethic, esthetic, etc. (see Vialati (1971) for Welby's correspondence with Giovanni Vailati [1863–1909] and Hardwick (1977) for her correspondence with Charles S. Peirce [1839–1914].)

Central to significs is Welby's triadic model for the analysis of meaning, the distinction between 'sense,' 'meaning,' and 'significance' (Welby, 1985[1893], 1985[1896], 1983[1903]: 5–6). As specified in her encyclopedia entry, "Significs": "Sense" refers to "the organic response to environment" and "essentially expressive element in all experience"; "Meaning" is purposive and refers to the specific sense which a word "is *intended to convey*"; "Significance," which includes sense and meaning and transcends them, refers to "the far-reaching consequence, implication, ultimate result or outcome of some event or experience" (Welby, 1977[1911]: 169). According to Peirce, Welby's meaning triad relates closely to his own triadic distinction between Immediate Interpretant, Dynamical Interpretant, and Final Interpretant (in Hardwick, 1977: 109–111).

A provisional definition of significs was formulated by Welby in *Significs and Language* (1911): "the study of the nature of significance in all its forms and relations" (Welby, 1985[1911]: vii), with a practical bearing "not only on language but on every possible form of human expression in action, invention, and creation" (ix). Furthermore, as specified in *What is meaning?*, significs as the "philosophy of Significance" involves the "philosophy of Interpretation, of Translation, and thereby of a mode of synthesis accepted and worked with by science and philosophy alike" (Welby, 1983[1903]: 161).

In addition to a theory of meaning, significs develops a 'significal method' that transcends pure descriptivism and strictly logico-epistemological boundaries in the direction of axiology and of the study of the conditions that make meaningful behavior possible. Significs is "a method of mental training" which concentrates intellectual activities on "meaning," the main value and condition for all forms of study and knowledge (Welby, 1983[1903]: 83). Again, significs is "a method of observation, a mode of experiment" which "includes the inductive and deductive methods in one process" (161).

The scope and reference of significs is universal, so that the term 'significs' designates a *transdisciplinary* approach and not a "supplanting system." Most significantly: "The principle involved forms a natural self-acting Critique of every system in turn, including the common-sense ideal" (Welby, 1983[1903]: 162), therefore significs is also *metadisciplinary.*

Significs is the expression of 'cooperating minds' in a community context. Welby worked on her ideas in dialogue with others, and particularly through an international network of epistolary relations with over 450 correspondents. In addition to Peirce and Vailati, these included Bertrand Russell, John M. Baldwin, Herbert Spencer, Thomas A. Huxley, Max Müller, Benjamin Jowett, Frederick Pollock, George F. Stout, H. G. Wells, Mary E. Boole, Henry and William James, Henri L. Bergson, Michel Bréal, André Lalande, J.-H. Poincaré, Ferdinand Tönnies, Rudolph Carnap, Otto Neurath, Harald Höffding, and Frederik van Eeden. Accordingly, Welby believed that significs could not be attached to any individual name.

'Significs' is a term coined by Victoria Lady Welby (1837–1912, England) in 1896 for her theory of meaning and interpretation, which she developed in terms of the relation between sign, value, and behavior. Significs focuses on the sign's ultimate value and significance beyond semantic meaning and as such keeps account of the everyday expression, "What does it signify?" In contrast to such terms as 'semantics,' 'semasiology,' or 'semiotics,' 'significs' was free from technical associations. It follows that it was suitable to signal the axiological implications in the relation between sign and meaning, therefore the connection between sign and value in all its aspects – pragmatic, social, ethic, esthetic, etc. (see Vialati (1971) for Welby's correspondence with Giovanni Vailati [1863–1909] and Hardwick (1977) for her correspondence with Charles S. Peirce [1839–1914].)

Central to significs is Welby's triadic model for the analysis of meaning, the distinction between 'sense,' 'meaning,' and 'significance' (Welby, 1985[1893], 1985[1896], 1983[1903]: 5–6). As specified in her encyclopedia entry, "Significs": "Sense" refers to "the organic response to environment" and "essentially expressive element in all experience"; "Meaning" is purposive and refers to the specific sense which a word "is *intended to convey*"; "Significance," which includes sense and meaning and transcends them, refers to "the far-reaching consequence, implication, ultimate result or outcome of some event or experience" (Welby, 1977[1911]: 169). According to Peirce, Welby's meaning triad relates closely to his own triadic distinction between Immediate Interpretant, Dynamical Interpretant, and Final Interpretant (in Hardwick, 1977: 109–111).

A provisional definition of significs was formulated by Welby in *Significs and Language* (1911): "the study of the nature of significance in all its forms and relations" (Welby, 1985[1911]: vii), with a practical bearing "not only on language but on every possible form of human expression in action, invention, and creation" (ix). Furthermore, as specified in *What is meaning?*, significs as the "philosophy of Significance" involves the "philosophy of Interpretation, of Translation, and thereby of a mode of synthesis accepted and worked with by science and philosophy alike" (Welby, 1983[1903]: 161).

In addition to a theory of meaning, significs develops a 'significal method' that transcends pure descriptivism and strictly logico-epistemological boundaries in the direction of axiology and of the study of the conditions that make meaningful behavior possible. Significs is "a method of mental training" which concentrates intellectual activities on "meaning," the main value and condition for all forms of study and knowledge (Welby, 1983[1903]: 83). Again, significs is "a method of observation, a mode of experiment" which "includes the inductive and deductive methods in one process" (161).

The scope and reference of significs is universal, so that the term 'significs' designates a *transdisciplinary* approach and not a "supplanting system." Most significantly: "The principle involved forms a natural self-acting Critique of every system in turn, including the common-sense ideal" (Welby, 1983[1903]: 162), therefore significs is also *metadisciplinary.*

Significs is the expression of 'cooperating minds' in a community context. Welby worked on her ideas in dialogue with others, and particularly through an international network of epistolary relations with over 450 correspondents. In addition to Peirce and Vailati, these included Bertrand Russell, John M. Baldwin, Herbert Spencer, Thomas A. Huxley, Max Müller, Benjamin Jowett, Frederick Pollock, George F. Stout, H. G. Wells, Mary E. Boole, Henry and William James, Henri L. Bergson, Michel Bréal, André Lalande, J.-H. Poincaré, Ferdinand Tönnies, Rudolph Carnap, Otto Neurath, Harald Höffding, and Frederik van Eeden. Accordingly, Welby believed that significs could not be attached to any individual name.

Important figures in Welby's time were influenced by significs, including Charles K. Ogden. He mentions her theory of meaning in his 1923 book with Ivor A. Richards, *The Meaning of Meaning*, and signals her correspondence with Peirce (which presents his important writings on "existential graphs"; see Hardwick, 1977).

Through mediation of the poet and psychologist Frederik van Eeden (1860–1932), Welby's Significs gave rise to the Significs Movement in the Netherlands in the first half of the twentieth century.

Welby's published and unpublished writings, including her mostly unpublished correspondence, are available in the Welby Collection, York University Archives and Special Collections, Toronto (Canada) and in the Lady Welby Library, University of London Library (England). For information on publications in Significs and the Significs Movement, see Petrilli (1990, 1998a, 1998b, 2005a); Schmitz (1985, 1988, 1990); and Schmitz and Heijerman (1991).

Silence

A Jaworski, Cardiff University, Cardiff, UK

© 2006 Elsevier Ltd. All rights reserved.

What monochrome painting, in its richness and multitude of manifestations is to history of art, silence is (or should be) to linguistics. Functionally, the question what silence 'does' is best answered in the same way as is the question what speech, or any other semiotic system, can 'do' in communication. Taking Halliday's (1978) view of semiotic systems, for example, silence can be shown to fulfill three major functions: ideational, interpersonal and textual (*see* **Systemic Theory; Halliday, Michael A. K. (b. 1925)**).

Important figures in Welby's time were influenced by significs, including Charles K. Ogden. He mentions her theory of meaning in his 1923 book with Ivor A. Richards, *The Meaning of Meaning*, and signals her correspondence with Peirce (which presents his important writings on "existential graphs"; see Hardwick, 1977).

Through mediation of the poet and psychologist Frederik van Eeden (1860–1932), Welby's Significs gave rise to the Significs Movement in the Netherlands in the first half of the twentieth century.

Welby's published and unpublished writings, including her mostly unpublished correspondence, are available in the Welby Collection, York University Archives and Special Collections, Toronto (Canada) and in the Lady Welby Library, University of London Library (England). Silence

A Jaworski, Cardiff University, Cardiff, UK

© 2006 Elsevier Ltd. All rights reserved.

What monochrome painting, in its richness and multitude of manifestations is to history of art, silence is (or should be) to linguistics. Functionally, the question what silence 'does' is best answered in the same way as is the question what speech, or any other semiotic system, can 'do' in communication. Taking Halliday's (1978) view of semiotic systems, for example, silence can be shown to fulfill three major functions: ideational, interpersonal and textual (*see* **Systemic Theory; Halliday, Michael A. K. (b. 1925)**).

In its ideational function, i.e., describing or referring to the nonlinguistic reality, silence's primary function is to conceal information. But it can also allow ideational inferences to be made, as when a silent response follows a request for information. Consider the following (constructed) example:

A: Who ate all the cookies?
B: [silence]
A: I knew you did!

Not unlike other forms of nonverbal communication, what silence serves best is the interpersonal function, i.e., managing social actors' relations of power and solidarity. Thus, silence can either mark interpersonal intimacy or extreme distance in situations where 'small talk' is normally required between casual acquaintances (Jaworski, 2000); alternatively, it may signify an extreme power differential between interactants (Braithwaite, 1990) (*see* **Power and Pragmatics**). In its textual function of organizing coherence, or the framing of talk, pauses are often used to add emphasis to what is going to be said next (Duez, 1982), or they may occur before and during a stretch of talk marked as a performance (e.g., when reciting a poem) (Bauman, 1997) (*see* **Cohesion and Coherence: Linguistic Approaches**).

Silence has been studied more or less explicitly in most functionally oriented frameworks of linguistic analysis. Saville-Troike (1985) has offered a holistic view of silence from an ethnographic perspective, arguing that silence in the form of pauses and hesitations carries predominantly affective and connotative meaning, whereas silent communicative acts (such as responses to greetings, queries or requests) may carry propositional meanings on a par with other verbal communicative acts, such as questions, promises, denials, warnings, threats, insults, and so on (*see* **Speech Acts; Pragmatic Acts; Speech Acts, Literal and Nonliteral**). In Conversation Analysis, pauses have been identified as 'dispreferred seconds' (e.g., Davidson, 1984) such that, if an invitation is followed by a pause, other things being equal, it is most likely going to be interpreted as a 'refusal' (*see* **Conversation Analysis**). Numerous versions of Critical Discourse Analysis have focused on silence and silencing as forms of sociopolitical control and oppression (Gal, 1989; Theismeyer, 2003) (*see* **Critical Applied Linguistics**). Other approaches have included semiotics (Kurzon, 1998) and politeness theory (Sifianou, 1997) (*see* **Semiotics: History; Politeness**). Many studies have been concerned with crosscultural differences in the use and 'toleration' of silence, including differing attitudes to talk and nontalk, relative length of intra- and interturn pauses, and silence or volubility as sources of miscommunication (e.g., Philips, 1976; Scollon, 1985; Enninger, 1987; Jaworski & Sachdev, 2004) (*see* **Intercultural Pragmatics and Communication**).

Another productive way of studying silence is by examining specific domains of language use and genres of communication in which silence plays a prominent communicative or expressive role. These include ritual (including religious) communication (cf. Bauman, 1983), censorship (Jaworski, 1993; Jaworski and Galasiński, 2000), literature and performance art (Tannen, 1990; Jaworski, 1998) (*see* **Ritual and Religious Language; Narrativity and Voice; Literary Pragmatics**).

Silence: Cultural Aspects

M Saville-Troike, University of Arizona, Tucson, AZ, USA

Silence as a Signifier

Silence, perhaps because it is typically defined as the absence of acoustic signals, has long been neglected in linguistics. Nevertheless, it is an essential component of communication, and people who are members of the same speech community share as much in the uses and interpretations they give to silence as they do in regard to the linguistic forms that they use. Silence is a 'signifier' in Saussure's sense of a meaningful element that is linked to a referent by cultural convention. As with spoken language, the linkage between silence and meaning may be symbolic, indexical, or iconic. The symbolic link of silence to meaning is arbitrary, with segments of silence assigned referential meaning much as speech segments are (e.g., /hors/ in English for the four-legged creature that eats hay). For example, *a moment of silence* may mean 'respect,' or silence in response to a request may mean either 'yes' or 'no,' depending on which interpretation has been assigned to it in particular contexts by the speech community. The indexical link of silence to meaning essentially involves the association of ideas. This level of signification goes beyond the literal content of messages and requires understanding of the interpretive frames within which they occur, as when silence indexes social relationships. The iconic link between form and meaning is a more direct and 'natural' one, although it is also importantly related to cultural considerations. Silence has meaning at this level, for example, in its representation of 'death.' This meaning is invoked in such metaphors as *the silence of the tomb*, and in Hamlet's final utterance: *The rest is silence*.

In contrast to its relative neglect within linguistics, silence has been accorded widespread attention in philosophy, anthropology, and literary analysis. A search for *silence* and *silent* in the *MLA International Bibliography* website, for example, yields over 3000 entries, most related to the role of silence as a sociocultural signifier.

Cultural Meanings and Social Distribution

Ultimately all aspects of culture are potentially relevant to the domain of silence, but those that have the most direct bearing on this topic are social and institutional structure, values and attitudes held about language and speaking (or not speaking), and ways in which communicative knowledge and skills (including appropriate use of language and silence) are transmitted from one generation to the next and to new members of the group.

Aspects of social structure that are indexed by silence commonly involve interaction phenomena that reflect status and role. Speech may be proscribed, for example, from a commoner to a chief, or between a man and his mother-in-law. Where power is accorded voice, silence is often indicative of powerlessness.

Silence as a Signifier

Silence, perhaps because it is typically defined as the absence of acoustic signals, has long been neglected in linguistics. Nevertheless, it is an essential component of communication, and people who are members of the same speech community share as much in the uses and interpretations they give to silence as they do in regard to the linguistic forms that they use. Silence is a 'signifier' in Saussure's sense of a meaningful element that is linked to a referent by cultural convention. As with spoken language, the linkage between silence and meaning may be symbolic, indexical, or iconic. The symbolic link of silence to meaning is arbitrary, with segments of silence assigned referential meaning much as speech segments are (e.g., /hors/ in English for the four-legged creature that eats hay). For example, *a moment of silence* may mean 'respect,' or silence in response to a request may mean either 'yes' or 'no,' depending on which interpretation has been assigned to it in particular contexts by the speech community. The indexical link of silence to meaning essentially involves the association of ideas. This level of signification goes beyond the literal content of messages and requires understanding of the interpretive frames within which they occur, as when silence indexes social relationships. The iconic link between form and meaning is a more direct and 'natural' one, although it is also importantly related to cultural considerations. Silence has meaning at this level, for example, in its representation of 'death.' This meaning is invoked in such metaphors as *the silence of the tomb*, and in Hamlet's final utterance: *The rest is silence*.

In contrast to its relative neglect within linguistics, silence has been accorded widespread attention in philosophy, anthropology, and literary analysis. A search for *silence* and *silent* in the *MLA International Bibliography* website, for example, yields over 3000 entries, most related to the role of silence as a sociocultural signifier.

Cultural Meanings and Social Distribution

Ultimately all aspects of culture are potentially relevant to the domain of silence, but those that have the most direct bearing on this topic are social and institutional structure, values and attitudes held about language and speaking (or not speaking), and ways in which communicative knowledge and skills (including appropriate use of language and silence) are transmitted from one generation to the next and to new members of the group.

Aspects of social structure that are indexed by silence commonly involve interaction phenomena that reflect status and role. Speech may be proscribed, for example, from a commoner to a chief, or between a man and his mother-in-law. Where power is accorded voice, silence is often indicative of powerlessness.

Thus women may be required to keep silent in the presence of men, or children in the presence of adults. The opposite is the case in settings where self-exposure is required, and where the listener sits in silent judgment: e.g., in religious confession, psychotherapy, bureaucratic interviews, and jury trials. The amount of talk versus silence that is prescribed is closely tied to social values and norms, and can only be interpreted in its cultural context.

Components of the interpretive frame that defines interactional silence include the physical and temporal setting, the type (or genre) of event, its general purpose and topic, the identity and relationship of participants, and the textual sequence (what has preceded and what is expected to follow). This interpretive frame is situated within the larger context of societal institutions, beliefs, and norms. Non-interactional silence may merely indicate absence of activity, but it too is imbued with conventional meaning when it is the frame for such contemplative and meditative events as that invoked in the Judeo-Christian call to worship: *The Lord is in His holy temple; let all the earth keep silence before Him*. Other sociocultural functions include marking boundaries of events and serving as a background against which speech and other activity is interpreted.

In some cases, the meaning of silence may be defined by a society's covenants and laws. In the United States, for instance, suspected legal offenders must be explicitly informed that they have the 'right to remain silent' to avoid self-incrimination, although in other legal contexts a person may commit perjury by silence. Instances of implicit silence (i.e., non-disclosure) in business transactions have been ruled to constitute active concealment and fraud. In some societies, silence in interpersonal interaction may be invoked as a powerful instrument of social control (e.g., 'shunning' among the Eskimo, the Igbo, or the Amish).

Acquisition of communicative competence requires learning the appropriate usage of silence in a community as well as of speech. Because cultural beliefs, values, and practices are integrally involved in the process, socializing young children or new group members to the meaning of silence may be considered part of the transmission of worldview.

Study of Silence

Silence is often not documented because it does not attract attention in the same way that audible or visible behavior does. Norms for appropriate use in specific situations can perhaps most easily be inferred from the reaction of participants to their violation, or when explicit instruction or 'correction' is given to children or newcomers. Cultural beliefs and values concerning silence may also be distilled in proverbs: e.g., *Silence is golden* (English); *Because of the mouth the fish dies* (Spanish); and *Man becomes wise through the ear* (Farsi). Additionally, cultural understandings regarding the contextual or interactional interpretation of silence may be made explicit in the choice of adjectives coupled with the term *silence* itself (e.g., *ominous silence*, *reverent silence*, *eerie silence*, *smug silence*, *reflective silence*, *pregnant silence*) or may be implied by terms used to describe people who exhibit relatively silent behavior (e.g., *taciturn*, *reserved*, *secretive*, *circumspect*). Metaphorical references that link silence to seemingly unrelated objects and events provide insights into how people conceptualize their world and the meanings they accord silence in relation to other experiential domains.

As with study of other aspects of culture, the study of silence as a sociocultural signifier may be approached from functionalist, constitutive, and critical perspectives. Each of these informs and highlights different facets of the topic, and all may be needed to achieve adequate understanding. The functionalist approach is emphasized in viewing silence as a component of communication that functions in relation to such cultural categories as belief systems and social organization; the constitutive approach is emphasized in viewing silence as a dynamic interactional phenomenon that is involved in establishing role-relationships and expressing social identity; the critical approach is emphasized in viewing silence in relation to sociopolitical domination and subordination.

Asymmetries of Access to Speaking Privilege

Differential speaking privileges and responsibilities are allocated to individuals or classes of people who are engaged in communicative events. Some of these are institutionally-determined, with lower-status (less powerful) members of a society or organization usually accorded less access to speaking opportunities than higher-status persons. Institutionally-determined asymmetries in participation also result from ritual constraints on speech versus silence, such as who has a responsibility to speak or remain silent in religious services, legal proceedings, funerals, classes in school, and public performances (e.g., concerts and movies). Other asymmetries are group-determined, with differential access to speaking roles delegated (e.g., in legislative bodies and committees), or assigned as the implicit or explicit outcome of group dynamics. Still others are individually-determined, often by personality factors (e.g., the relative aggressiveness of participants), tactical strategies (e.g., concealment or image manipulation), and attitudes (e.g., respect or

disapproval). For example, silent attentiveness during relatively long stretches while one person 'holds the floor' may convey listener interest and respect, although the same absence of conversational backchannel noise in some speech communities (e.g., African-American) would convey indifference or hostility.

Position and Duration of Silence in Discourse

Discourse is both silence and sound. The former includes the pauses and hesitations that occur within and between turns of talk – the rhythmic patterns of silence. The meanings they carry are generally affective in nature, and typically connotative rather than denotative. These meanings may nonetheless be symbolic and conventional, as is seen in the various patterns of use and norms of interpretation in different speech communities. Cultural differences are particularly notable in the duration of pauses between turns, or 'switching' pauses. For example, certain American Indian groups are accustomed to waiting several minutes in silence before responding to a question or taking a turn in conversation, while the native English speakers they may be talking to have very short time frames for responses or conversational turn-taking, and find long silences distressful. For members of these particular American Indian groups, a shorter duration may be interpreted as impoliteness, and as not giving adequate consideration to the topic under discussion. For native English speakers, a longer duration may be interpreted as unfriendliness or shyness, lack of knowledge, or not wanting to be involved. In the context of legal proceedings, native English speakers are likely to (mis)interpret long pauses by defendants and witnesses as signs of lack of cooperation and of evasiveness, perhaps even of guilt.

The duration of pauses within speaking turns varies by cultural group membership, but it is influenced more by situational factors than are switching turns. Pauses may reflect time that is needed for mental search processes, especially in cognitively demanding speaking tasks, and there are pauses that reflect encoding difficulties. Duration of pausing is strongly influenced by whether the speech is preplanned or spontaneous.

The genre of discourse also influences pausing position and duration, with poetry reading, prose reading, spontaneous narratives, and conversations all showing different patterns of placement and duration of silence in relation to sound, whatever the cultural context.

Silence occurs in terminal positions within discourse as well as in switching and medial slots. Utterances and even whole communicative events may be completed in silence when the topic is a particularly delicate one or the word that would be used is taboo, or when the situation is emotionally loaded and the speaker is 'at a loss' for words. The Japanese term *haragei* 'wordless communication' captures the essence of this latter usage.

On one side, silence functions to structure discourse. On another, silence often conveys a message precisely because it forms part of discourses that are additionally structured by sound.

Special Group Uses of Silence

Cultural aspects of silence are often most dramatically apparent in special group uses of silence. These are typically associated with activity domain (e.g., religion) and with dimensions of power.

Extreme manifestations mark some religious group membership, as the vow of silence required by certain monastic orders. Silence is needed in Quaker worship services in order to allow 'space' in which God can work; in some ritual contexts, any speech at all is considered profane. The ban on speech is often associated with setting, with entry into a place of worship calling for silence even when no service is in progress. The silence is often accompanied by special patterns of head, hand, and body position and movement.

Silence is a signifier of power when it indexes the capacity of some individuals, groups, and institutions in a society to control others. From a critical perspective, most notable are coercive acts that force certain participants to speak, limit expression, or maintain silence. These may be institutionally prescribed for the maintenance of system and order, such as teachers' authority in school classrooms to control speaking rights, or judges' authority in courtrooms, or may be self-imposed by common agreement, as when a group adopts *Roberts' Rules of Order*. However, when whole classes of members of a society (such as women or members of certain ethnic, social, or religious groups) are compelled to remain silent by being denied speaking rights, their silence becomes a sign of oppression, and may even, to the discerning observer, 'speak louder than words.'

Silvestre de Sacy, Baron Antoine-Isaac (1758–1838)

V Raby, Université de Reims-Champagne-Ardenne, Reims, France

© 2006 Elsevier Ltd. All rights reserved.

Silvestre de Sacy was born on September 21, 1758, in Paris and died there on February 21, 1838. Silvestre was the surname of his father, a Parisian notary, and 'de Sacy' was added by his son. As early as 1781, Silvestre de Sacy became a counsellor in the Cour des monnaies and was appointed commisioner-general in 1791. During this time, he studied most Semitic languages and was able to decipher the Pahlavi inscriptions. In 1792, he retired from this position and became a member of the Académie des Inscriptions. He became the perpetual secretary of this institution in 1833. The Ecole des Langues Orientales Vivantes, founded in 1795, employed Silvestre de Sacy as a teacher of Arabic, and beginning in 1806 he also taught Persian at the Collège de France. From 1808 to 1814, he was a member of the Legislative Corps and was made a baron in 1813. From 1815 to 1820, he served on the Commission for Public Instruction and was rector of the University of Paris, and in 1822 he became a member of both the Collège de France and the Ecole des Langues Orientales Vivantes. In the same year he was joint founder with Abel Rémusat of the Société asiatique. In 1832 he became a peer of France, librarian of the Eastern manuscripts at the Royal Library, and inspector of oriental typefaces at the royal printing press.

Silvestre de Sacy was soon recognized as a great orientalist. His *Grammaire arabe*, *Chrestomathie arabe*, and *Anthologie grammaticale* are still known as important textbooks. He contributed to the European knowledge of Eastern cultures by editing and translating early literature (*Calila et Dimna*, Hariri's *Maqamat* with an Arabic commentary, the *Alfiyya*) and a version of Abd al Latif's *Relation arabe sur l'Egypte*. He studied property law in Egypt and provided editions of the Arabic and Syrian New Testament texts for the British and Foreign Bible Society. His lifetime work, a study on the religion of the Druzes (*Exposé de la religion des Druzes*), was unfinished. In addition to oriental studies, and as a preparation to his *Grammaire arabe*, Silvestre de Sacy wrote a general grammar (*Principes de Grammaire Générale mis à la portée des enfants*) in 1799. Along with its educational value, this textbook provides a synthesis of the main general grammars of the past (i.e., the works of Port-Royal, Beauzée, and Court de Gebelin), adding references to Eastern and Semitic languages. A major feature of this grammar is its description of the subordinate clause introduced by the conjunction *que* (the so-called *proposition complémentaire*) as a proper type of subordinate clause. De Sacy's scholarly colleagues at the Collège de France and the Ecole des Langues orientales Vivantes (G. Flügel, H. G. L. Kosegarten, E. M. Quatremère, W. de Slane, and H. L. Fleischer) contributed to the dissemination and growth of Arabic studies and knowledge in the 19th century.

Sinclair, John M. (b. 1933)

J Léon, CNRS, Univeristy of Paris 7, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

John McHardy Sinclair is a well-known linguist who has contributed substantially to several areas of scientific language study, including lexicography, discourse analysis, and computational linguistics. He is a leading figure in current corpus-based language research (Baker *et al.,* 1993).

He was born in 1933 in Great Britain, and graduated in English Language and Literature at Edinburgh University, where he was appointed to a lectureship in the Department of English and General Linguistics in 1958. In 1965, he was elected to the foundation chair of Modern English Language at the University of Birmingham, where he took a very active part in developing Modern English Language teaching. Since his retirement in 2000, he has been Emeritus Professor of English Language and Linguistics at the University of Birmingham and has continued his research at the Tuscan Word Center, which he founded in 1995 in Italy.

At Edinburgh University in 1961, John Sinclair planned with Michael A. K. Halliday to collect a corpus of spontaneous English speech in order to study sentence structure and lexical collocation, thus joining the pioneering trend of computerized corpora flourishing at that time, such as the British *Survey of English usage* (1960), the French *Trésor de la langue Française* (1960), and the American *Brown corpus* (1967). From their acquaintance with the London School, Sinclair and Halliday regarded lexicogrammar as a proper field, denying strict boundaries between grammar and lexis. Moreover, Sinclair borrowed from Firth the notion of collocation, which he implemented in computational studies of English lexis (Sinclair, 1966; Sinclair *et al.,* 1970, Jones and Sinclair, 1974) and corpus research (Sinclair, 1991). His concerns with the uses and usability of texts led him to work, in association with his colleagues of the University of Birmingham, Malcolm Coulthard and David Brazil, on discourse analysis and its application to English teaching (Sinclair and Coulthard, 1975, Sinclair and Brazil, 1982). In 1980, Sinclair initiated the Cobuild project in computational lexicography, based on a large corpus of English language texts, and devoted himself to the design of dictionaries and grammars from collocations (Sinclair, 1987). In addition to practical concerns, such as teaching, dictionaries, and grammars, corpus-based research led him to address more theoretical issues. He coined the word 'naturalness' to account for the fact that most examples chosen by linguists are not natural, although they are well formed. Well-formedness is absolute, while naturalness is probabilistic, that is, corpus-dependent. His hypothesis is that any instance of language depends on its surrounding context, so he attempted to promote naturalness as textual well-formedness (Sinclair, 1984, 1991).

Sindhi

J Cole, University of Illinois, Urbana-Champaign, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Sindhi is an Indo-Aryan language with its roots in the lower Indus River valley. It takes its name from the Indus River, known in earlier times as the Sindhu. Today Sindhi is spoken in the province of Sindh, Pakistan, where it is recognized by the government as the official language of the province, home to an estimated 30–40 million people (projected from 1981 census data). Nearly half of the population of Sindh lives in rural areas, where Sindhi is the primary language. In the urban centers of Sindh, Sindhi competes for status and speakers with Urdu (the national language of Pakistan) and, increasingly, English. Sindhi is also spoken by about 2.5 million people in India, including major communities in Gujarat, Mumbai, and Pune, where immigrants from Sindh relocated after the 1947 partition of India and Pakistan. Beyond the Indian subcontinent, Sindhi is spoken by large diaspora communities in the United Kingdom and the United States, and around the world.

Language History

Sindh is the site of the ancient Harappan civilization of the lower Indus River valley. A case can be made that remnants of Harappan culture are evident in classical Sindhi folklore and religious rituals, which raises the question of a possible linguistic link between Sindhi and the Harappan language. Unfortunately, there is little evidence on which to determine the linguistic stock of the Harappan language, the ancient script is as yet undeciphered, but a prevailing theory suggests a Dravidian origin. This theory points to the presence of the Dravidian language Brahui, spoken in the northwestern Pakistani province of Baluchistan, as a remnant of a broader Dravidian region in the subcontinent in earlier times. This possible link to an ancient Dravidian language of the Harappans has led some scholars to claim a Dravidian origin for Sindhi. This minority view, however, clashes with a substantial body of linguistic evidence for an Indo-Aryan origin of Sindhi.

The earliest historical reference to Sindhi is in the *Nātyaśāstra*, a dramaturgical text that was written between 200 B.C. and 200 A.D. Evidence for Sindhi as a written language dates to a translation of the Islamic *Qur'an* in 883 A.D., followed a century later by a Persian translation of the ancient Indian religious epic *Mahābhārata* taken from a language thought to be Old Sindhi. Dating the emergence of Sindhi in the evolution of Indo-Aryan is a matter of some controversy. Various theories, ably summarized by Khubchandani (2000), trace Sindhi to the Vrācaḍa Apabhramśa or to an earlier pre-Vedic Prakrit language. Although Trumpp (1872), in his authoritative Sindhi grammar, describes Sindhi as a more 'pure Sanskritical' language compared to the other modern Indo-Aryan languages, Sindhi undeniably reveals the impact of its long history of contact with speakers of other languages.

Sindh has succumbed to foreign rule many times over a history of 2500 years and, much like English, has accumulated linguistic features and vocabulary from the languages of its foreign rulers. In pre-Muslim history, from the 6th century B.C. through the 1st century A.D., Sindh was invaded by a succession of Achamenian, Greek, Mouryan, Scythian, and Persian rulers, including Alexander the Great (329–324 B.C.). After a brief period of rule by local dynasties, the Arab invasion in 711 A.D. initiated the Muslim period and the heavy influence of Persian on Sindhi with numerous lexical borrowings. Following a period of rule by local dynasties from the 11th through the mid-19th century, Sindh joined the British Empire in 1843. The influence of English on Sindhi, especially through lexical borrowings, began at that time and continues in the present, and is second only to Persian (Western Farsi) in its impact on the language. The result of language contact in all these periods of foreign rule is a Sindhi lexicon with diverse etymological bases and multiple cognate forms, which is further complicated by an exceptional number of irregular verbal inflections, and by the expansion of the sound inventory to include several Perso-Arabic sounds not native to Indo-Aryan.

Related Languages and Dialects

Among the languages spoken in the region today, Sindhi is closely related to Sirāikī (Saraiki), spoken north of Sindh province, and to Kachchhī (Kachchi), spoken in the Kachchh region of Gujarat, along the border between Pakistan and India. Grierson's (1919) survey listed five regionally defined Sindhi dialects, with Vicholī ('Central') as the standard variety. Contemporary dialectal work has been carried out by Khubchandani (1962–1963) and Rohra (1971) on Kachchhī (also spelled Kachhi, Kachchhi). Bughio's (2001) sociolinguistic study of the urban and rural Vicholī varieties is the only work since Grierson to deal with Sindhi dialect variation within Pakistan, and opened the door for promising future investigation.

Linguistic Features

Sound System

Sindhi and the neighboring languages Sirāikī and Marwari are distinct among Indo-Aryan languages for their use of the glottal implosive stops /ɓ, ɗ, ʃ, ɠ/, which derive from Middle Indo-Aryan geminate voiced stops in medial position and single voiced stops in initial position. In other respects, the sound inventory of Sindhi is typical of Indo-Aryan, with a full series of voiceless, voiced, aspirated, and voiced aspirated stops and nasal stops at five places of articulation (see Table 1). Alongside the alveolar rhotic tap [r] there is a retroflex tap [ɽ]; but unlike [r], the retroflex tap is restricted to intervocalic position, where it can be considered the positional variant of the retroflex stop [ɖ]. Retroflex [ɖ] occurs intervocalically only in a few English loan words, where it corresponds to the English alveolar [d], as in *loɖiŋga* 'truck' and *reɖiyo* 'radio' (from English *loading*, *radio*). Sindhi has incorporated a number of consonants from Persian, including the well-established sounds /f, v, ʃ, z, χ/, along with /q, ɣ/, which are not typically used except by urban, educated speakers for whom they are arguably reinforced by their stable presence in Urdu.

Sindhi has the standard Indo-Aryan vowel inventory with ten vowels that can be grouped in five long–short pairs: /i, iː, e, eː, u, uː, o, oː, a, aː/. The short mid vowels are subject to dialectal variation or merger (discussed below). Long vowels can occur with contrastive nasalization; compare the final long nasal vowels in *saːmhoː̃* 'in front of' and *vitʃʰuː̃* 'scorpion', with the final long oral vowels in *sanhoː* 'thin' and *kaduː* 'gourd'. Phonetically nasal short vowels occur in the context of a following tautosyllabic nasal consonant, e.g., *ãmbu* 'mango', but can also occur in an open syllable preceding or following /h/, where they contrast with oral short vowels. Compare the short nasal vowels in *mũhũ* 'mouth', *jĩhĩ* 'who/relative pronoun' with the short oral vowels flanking /h/ in *mahalu* 'palace', *subahu* 'morning'.

Sindhi syllable structure allows for at most one consonant to appear in the onset and coda position (CVC). Consonant clusters (CC) occur word medially, as in CV<u>C.C</u>V *kursiː* 'chair'. With a few loanword exceptions, Sindhi words must end in a vowel. Short vowels in word-final position are extremely reduced, though grammatically important as markers of noun number, gender and case. Vowel-initial syllables may occur initially and medially, and in the latter case may give rise to word-internal vowel sequences (hiatus), as in *bʰaːʃaːiː* 'brother's wife'. Hiatus sequences never occur with identical vowels.

There are several features of Sindhi pronunciation that are subject to dialectal variation, distinguishing the speech of rural, uneducated, or older speakers who represent an older variety of Sindhi, from urban, educated (i.e., literate) or younger speakers, whose speech is more noticeably influenced by Urdu, Hindi, and English pronunciation patterns. Three dialectal features described by Bughio (2001) are as follows. The short vowels /e, o/ are typically merged with their long counterparts in the old variety, resulting in [e, o] while new variety speakers more frequently keep them distinct, producing long monophthongs [eː, oː] and short diphthongs [ɑɪ, ɑʊ] or lax vowels [ɛ, ɔ]. The diphthong realization is typical of Muslim new variety speakers, and the lax vowels are typical of Hindu new variety speakers. This distinction based on religious affiliation reflects in part the separation of Hindu and Muslim communities since the 1947 partition of India and Pakistan, and the maintenance of diphthongs in Arabic loan words (borrowed through Persian) in the speech of both Sindhi- and Urdu-speaking Muslims. Old and new varieties of Sindhi are also distinguished by the frequent deletion or total loss of the word-final short vowels in the new varieties. The third dialectal feature in Sindhi is the pronunciation of the retroflex stops

Table 1 The consonants of Sindhi

	Labial	*Dental*	*Alveolar*	*Post-alveolar*	*Palato-alveolar*	*Velar*	*Glottal*
Stop	p b pʰ bʰ	t d tʰ dʰ		ʈ ɖ ʈʰ ɖʰ		k g kʰ gʰ	
Implosive	ɓ		ɗ		ʃ	ɠ	
Affricate					tʃ dʒ tʃʰ dʒʰ		
Nasal	m		n	ɳ	ɲ	ŋ	
Fricative	f		s (z)		(ʃ)	(x ɣ)	h
Rhotic			r	(ɽ) ɽʰ

Table 2 Nominal declensions for masculine and feminine nouns

		Nominative	*Oblique*	*Ablative*	*Vocative*
'boy'	Singular	tʃʰokiro:	tʃʰokire:	tʃʰokirã:	tʃʰokira:
	Plural	tʃʰokira:	tʃʰokirani	tʃʰokiraniã:	tʃʰokira:
'table'	Singular	meza	meza	mezã:	meza
	Plural	mezũ:	mezuni	mezuniã:	mezũ:

/ʈ, ɗ, ɗʰ/ as stop-rhotic clusters [ʈr, ɗr, ɗʰr] in the old varieties.

Morphology

Sindhi has a rich system of nominal and verbal morphology, with regular paradigms of declension and conjugation that exist alongside a remarkably high number of exceptional forms. Nouns, adjectives, and pronouns are marked for number, gender, and case. The gender class of the noun is in most cases marked by the final vowel, and number and case marking are expressed through a combination of stem alteration and final vowel suffix. Examples of nominal declension are shown with paradigms for the masculine noun 'boy' and feminine noun 'table' in Table 2.

Cases other than the ones shown in Table 2 are marked through the use of a postposition following the noun in the oblique singular form, for example *gʰara kʰe* 'to the house' (dative), *gʰara kʰã:* 'from the house' (ablative), *gʰara sã:* 'with the house' (comitative), *gʰara mẽ:* 'in the house' (locative), *gʰara jo:* 'of the house' (genitive). The genitive postposition is unique in that it is declined like an adjective, agreeing with the possessed noun in number, gender and case, as in (1):

(1) tʃʰokire ja:
boy.MASC.sing.OBL GEN.MASC.pl.NOM
kita:ba
book.MASC.pl.NOM
'the boy's books'
tʃʰokire ji:
boy.MASC.sing.OBL GEN.FEM.sing.NOM
ɓili:
cat.FEM.sing.NOM
'the boy's cat'

Sindhi verbs are marked for aspect, tense, mood, and concordance (gender and number) through a complex system of modification of the verb stem, which may in addition be followed by a modal and an auxiliary verb. These elements combine in various ways to produce 17 distinct finite verb forms, and six nonfinite verb forms that function as nominal, adjectival, and adverbial participles. Each finite and nonfinite verb form can undergo further modification of the verb stem to express voice (active/passive) and valence (transitive/causative) distinctions. Several finite forms of the verb *likʰaɳu* 'to write', all expressing masculine, singular concordance, are illustrated in Table 3.

Table 3 Example verb forms based on the root *likʰ*-'write'

Present unspecified	likʰe tʰo	'he writes'
Definite future	likʰando	'he will write'
Present habitual	likʰando a:he	'he writes (habitually)'
Present continuous	likʰi: rahiyo a:he	'he is writing'
Unspecified perfective	likʰiyo	'he wrote'
Subjunctive perfective	likʰiyo huje	'he may have written'
Imperative	likʰu likʰo	'Write!' (familiar) 'Write!' (polite)

Syntax

The pragmatically neutral word order in Sindhi is Subject-Object-Verb, but the order of these major constituents can be changed to put a phrase with Topic focus at the front of the sentence. Within phrases, the head element always occurs at the end, as in the noun phrase and verb phrase examples in (2):

(2) hi:a nandʰri: ʈopi:
this small hat
'this small hat'
ama: kʰe tʃiʈʰi: likʰi:
mother DAT letter wrote
'wrote a letter to mother'

The verb typically agrees with a nominative case-marked subject, as in

hu:a atʃe tʰi:
she-NOM come-3sing aux.FEM
'she comes'.

An 'experiencer' subject of a verb expressing physical state, psychological state, or kinship is marked with the dative postposition, as in

huna kʰe ɓukʰi laɠi:
he-OBL. DAT hunger-FEM strikes-FEM.sing.
'he is hungry'.

Sindhi has the split-ergative agreement pattern found in other Indo-Aryan languages, whereby in

the perfective aspect the subject of a transitive verb is marked for oblique case, and the verb agrees with a nominative (inanimate) object if present, and otherwise displays a default agreement (3sing.MASC).

Linguistic Works on Sindhi

Among published grammatical works on Sindhi, there are several grammars in the Sanskritic tradition, including Stack (1849), Trumpp (1872), and a section in Grierson's *Linguistic survey of India* (1919). Contemporary linguistic studies include instrumental phonetic studies (Nihalani, 1986, 1995), sociolinguistic and dialect studies (Rohra, 1971; Bhugio, 2001), and contemporary grammatical analysis (Khubchandani, 1961). Khubchandani (2000) presents a comprehensive bibliography of works on Sindhi from 1947–1967.

Singapore: Language Situation

L Lim and U Ansaldo, Universiteit van Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The Republic of Singapore's resident population of 3 263 200 comprises 76.8% Chinese, 13.9% Malay, 7.9% Indian, and 1.4% 'Others'; these are, however, only official race groupings with much internal ethnic and linguistic variation. Four languages have official status: Mandarin Chinese, Malay, Tamil – to represent the three main official races, with Malay being the national language for historical reasons – and English. Numerous other languages are also widely used in the community in a polyglossic situation.

Chinese languages such as Hokkien (Chinese, Min Nan, Xiamen) (approximately 42% of Chinese population), Teochew (Chinese, Min Nan, Chaoshan) (22%), Cantonese (Chinese, Yue) (15%), Hainanese (Chinese, Min Nan, Hainan) (7%), Hakka (7%), and Foochow (Chinese, Min Dong, Fuzhou) (2%) are robust within the respective speech communities. Mandarin has, however, shown a marked increase in usage in Chinese households (35% in 2000 from 24% in 1990), at the expense of the other Chinese languages (24% from 40%), reflecting the government's annual campaign since 1979 promoting the use of Mandarin over the other Chinese languages (referred to as 'dialects' in Singapore). Still, these so-called Chinese dialects have been increasingly and significantly used in political rally speeches in recent years, in a bid to connect more with the majority heartland populace.

Over half the Indian population in Singapore is Tamil, and Tamil is the dominant home language in 43% of Indian households. Malayalam, Punjabi (Panjabi), Hindi, Bengali, Gujarati, and Sinhala are also spoken by the respective speech communities. Malay is by far the most significant dominant home language in Malay households at 92%, and languages of Indonesia such as Javanese are also spoken in the respective ethnic groups. In the Peranakan or Straits Chinese community comprising some 10 000 in Singapore, Baba Malay, a mixed Hokkien-Malay

the perfective aspect the subject of a transitive verb is marked for oblique case, and the verb agrees with a nominative (inanimate) object if present, and otherwise displays a default agreement (3sing.MASC).

Linguistic Works on Sindhi

Among published grammatical works on Sindhi, there are several grammars in the Sanskritic tradition, including Stack (1849), Trumpp (1872), and a section in Grierson's *Linguistic survey of India* (1919). Contemporary linguistic studies include instrumental phonetic studies (Nihalani, 1986, 1995), sociolinguistic and dialect studies (Rohra, 1971; Bhugio, 2001), and contemporary grammatical analysis (Khubchandani, 1961). Khubchandani (2000) presents a comprehensive bibliography of works on Sindhi from 1947–1967.

Singapore: Language Situation

L Lim and U Ansaldo, Universiteit van Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The Republic of Singapore's resident population of 3 263 200 comprises 76.8% Chinese, 13.9% Malay, 7.9% Indian, and 1.4% 'Others'; these are, however, only official race groupings with much internal ethnic and linguistic variation. Four languages have official status: Mandarin Chinese, Malay, Tamil – to represent the three main official races, with Malay being the national language for historical reasons – and English. Numerous other languages are also widely used in the community in a polyglossic situation.

Chinese languages such as Hokkien (Chinese, Min Nan, Xiamen) (approximately 42% of Chinese population), Teochew (Chinese, Min Nan, Chaoshan) (22%), Cantonese (Chinese, Yue) (15%), Hainanese (Chinese, Min Nan, Hainan) (7%), Hakka (7%), and Foochow (Chinese, Min Dong, Fuzhou) (2%) are robust within the respective speech communities. Mandarin has, however, shown a marked increase in usage in Chinese households (35% in 2000 from 24% in 1990), at the expense of the other Chinese languages (24% from 40%), reflecting the government's annual campaign since 1979 promoting the use of Mandarin over the other Chinese languages (referred to as 'dialects' in Singapore). Still, these so-called Chinese dialects have been increasingly and significantly used in political rally speeches in recent years, in a bid to connect more with the majority heartland populace.

Over half the Indian population in Singapore is Tamil, and Tamil is the dominant home language in 43% of Indian households. Malayalam, Punjabi (Panjabi), Hindi, Bengali, Gujarati, and Sinhala are also spoken by the respective speech communities. Malay is by far the most significant dominant home language in Malay households at 92%, and languages of Indonesia such as Javanese are also spoken in the respective ethnic groups. In the Peranakan or Straits Chinese community comprising some 10 000 in Singapore, Baba Malay, a mixed Hokkien-Malay

variety, is spoken in the middle-older generations. In the 17 000-strong Eurasian community, a third of Portuguese-Malaccan descent, a creolized variety of Portuguese, Papia Kristang (Malaccan Creole Portuguese), is found in a few of the older generation. Most Baba and Eurasian households have English as the first language nowadays.

English has been since 1987 the medium of instruction in all schools (excluding the handful of officially recognized Malay-medium Muslim *madrasahs*), in a bilingual system where children learn as their second language (referred to as mother tongue) the official language matching their official ethnic group. With such cultivation of English-knowing bilingualism, the primary working language in Singapore has been recognized since the 1970s to be English, supplanting ubiquitous Bazaar Malay and Hokkien, which were until then Singapore's *lingua franca*. Literacy in English has risen steadily over the decades to 71%. Concurrent with this is the increase in the use of English as the dominant home language in all ethnic groups. English is also clearly more dominant in the younger generation. Code-mixing between the various languages is a salient feature of intra- and interethnic communication.

In linguistically heterogeneous Singapore, English has unsurprisingly evolved to display features resulting from language contact, particularly from Malay and Hokkien. While a more Standard Singapore English is still the variety found in more official, formal situations, Colloquial Singapore English, commonly known as Singlish, is widely used across generations and social classes, as well as in the media; as a reaction to the increasing prevalence of Singlish, the Speak Good English Movement was launched in 2000.

Sinhala

J W Gair, Cornell University, USA

© 2006 Elsevier Ltd. All rights reserved.

General

Sinhala (Sinhalese, Singhalese) is the first language of the majority in Sri Lanka, spoken by approximately 75% of the island's population (approximately 20 million in 2004) and thus has about 15 million first language speakers. It was declared the only official language of the country in 1956, but the status of official language was extended to the main minority language, Tamil, in 1987, with English as a link language. Sinhala belongs to the Indo-Aryan family and is thus related to languages of Northern India such as Hindi-Urdu, Panjabi, Bengali, and Marathi, and ultimately through Indo-European to English and the major Western European languages. Within Indo-Aryan, its closest relative is Dhivehi (Maldivian) of the Maldive islands (also on Minicoy, where it is known as Mahl) with which it forms a southern sub-group. These two languages have been isolated from their sister North Indian languages for over two millennia and have developed special characteristics of their own, many of them shared, though the languages are mutually unintelligible. They have also been significantly influenced by the neighboring Dravidian languages, particularly Tamil-Malayalam. One common Sinhalese Buddhist tradition states that the language was brought to the island from northeast India, on the date of the final passing of the Buddha (544–543 B.C.E in that tradition) though there are competing accounts. In any event, there are Sinhala inscriptions from the third and second centuries B.C.E. already showing changes distinguishing it from its sisters in India, most notably the complete loss of the aspirated consonant series, so that a date around the middle of the first millennium or shortly thereafter is not unreasonable. The place of origin has been disputed by serious scholars, one problem being that the time of separation predates the major changes that differentiate the Indian Indo-Aryan dialects. Recent work on historical phonology, however, does give some evidence for a generally eastern origin, along with dialect admixture.

The extant literature in Sinhala dates from the 9th–10th centuries, but it is clear from Pali texts and later references that there was an earlier body of works that was lost due to internal turbulence. Fortunately, there is an epigraphical record from the 3rd–2nd centuries B.C.E. on, so that we have a continuous record of the language from that time, an asset unmatched in any other modern Indo-Aryan language. The literary legacy is rich. Not surprisingly, given the cultural history of the island, much of it is Buddhist in content, encompassing both prose and poetry, but there is a flourishing current literary scene in virtually all genres, including poetry, novels, short stories, criticism, and a lively theatre. Literacy is high, approximately 89%, and near 100% in some areas, which contributes to this productivity.

Sinhala vocabulary includes words from many languages, including English, Dutch, Portuguese, and others as well as Dravidian. Sanskrit loans abound, especially in the technical and religious/philosophical spheres, but perhaps unexpectedly, given the prevalence of Theravada Buddhism, Pali loans are scarce.

General

Sinhala (Sinhalese, Singhalese) is the first language of the majority in Sri Lanka, spoken by approximately 75% of the island's population (approximately 20 million in 2004) and thus has about 15 million first language speakers. It was declared the only official language of the country in 1956, but the status of official language was extended to the main minority language, Tamil, in 1987, with English as a link language. Sinhala belongs to the Indo-Aryan family and is thus related to languages of Northern India such as Hindi-Urdu, Panjabi, Bengali, and Marathi, and ultimately through Indo-European to English and the major Western European languages. Within Indo-Aryan, its closest relative is Dhivehi (Maldivian) of the Maldive islands (also on Minicoy, where it is known as Mahl) with which it forms a southern sub-group. These two languages have been isolated from their sister North Indian languages for over two millennia and have developed special characteristics of their own, many of them shared, though the languages are mutually unintelligible. They have also been significantly influenced by the neighboring Dravidian languages, particularly Tamil-Malayalam. One common Sinhalese Buddhist tradition states that the language was brought to the island from northeast India, on the date of the final passing of the Buddha (544–543 B.C.E in that tradition) though there are competing accounts. In any event, there are Sinhala inscriptions from the third and second centuries B.C.E. already showing changes distinguishing it from its sisters in India, most notably the complete loss of the aspirated consonant series, so that a date around the middle of the first millennium or shortly thereafter is not unreasonable. The place of origin has been disputed by serious scholars, one problem being that the time of separation predates the major changes that differentiate the Indian Indo-Aryan dialects. Recent work on historical phonology, however, does give some evidence for a generally eastern origin, along with dialect admixture.

The extant literature in Sinhala dates from the 9th–10th centuries, but it is clear from Pali texts and later references that there was an earlier body of works that was lost due to internal turbulence. Fortunately, there is an epigraphical record from the 3rd–2nd centuries B.C.E. on, so that we have a continuous record of the language from that time, an asset unmatched in any other modern Indo-Aryan language. The literary legacy is rich. Not surprisingly, given the cultural history of the island, much of it is Buddhist in content, encompassing both prose and poetry, but there is a flourishing current literary scene in virtually all genres, including poetry, novels, short stories, criticism, and a lively theatre. Literacy is high, approximately 89%, and near 100% in some areas, which contributes to this productivity.

Sinhala vocabulary includes words from many languages, including English, Dutch, Portuguese, and others as well as Dravidian. Sanskrit loans abound, especially in the technical and religious/philosophical spheres, but perhaps unexpectedly, given the prevalence of Theravada Buddhism, Pali loans are scarce.

Varieties

While there is some regional dialect variation, all spoken dialects are mutually intelligible, requiring only some small adjustment. The main varietal difference is diglossia, involving two main functional varieties, generally referred to as Spoken Sinhala and Literary Sinhala. The former is used for all face-to-face communication, and the latter for virtually all written and published materials, except in some informal communication and in dialogue in modern fiction and drama, with the embedding narrative material generally in Literary. One major difference that has been taken as the defining characteristic of the varieties is that Literary Sinhala has subject-verb agreement, as in (1), while all of the Spoken varieties lack it, as in (2). There are also accompanying differences in morphology, case forms, and use, and in fact the varieties differ on all levels of structure except phonology, since oral presentations of Literary use the spoken repertory. Literary productions are virtually always written beforehand. There are subvarieties within each of the major ones, and a Formal Spoken variety lacking agreement but showing some Literary features such as lexicon and some case features is seeing increasing use, partly because of the need for live production in the media, as in interviews and speeches. Some news broadcasts now use that variety, though earlier they were written in Literary and read out.

(1) Literary (in transliteration):
mama goyam kapami.
I *rice-plants* *cut*-PRESENT-1SG
'I reap paddy.'

api goyam kapamu.
We *rice-plants* *cut*-PRESENT-1PL
'We reap paddy.'

ma:ma: goyam kapayi.
uncle *rice-plants* *cut*-PRESENT-3SG
'(Maternal) uncle reaps paddy.'

(2) Spoken (in phonological representation):
mamə/api/ma:ma goyaŋ kapənəwa.
I/we/uncle *rice-plants* *cut*-PRESENT
'I/we/maternal uncle reap paddy.'

Phonology

Two notable characteristics of the Sinhala phonological inventory that are shared with Dhivehi but that are different from other Indo-Aryan languages are the lack of aspirated consonant series and a series of prenasalized stops that contrast with nasal-stop clusters. The vowel and consonant inventories are shown in Table 1.

Table 1 The Sinhala consonant and vowel inventory

Consonants		*Vowels*		
Voiceless stops	k c ṭ t p	i i:		u u:
Voiced stops	g j ḍ d b			
Prenasalized stops	^{n}g (^{n}j) ^{n}ḍ ^{n}d ^{m}b	e e:	ə	o o:
Nasals	ŋ ñ n m			
Resonants, spirants	y r l w š s h	æ æ:		a a:

Orthography

Sinhala has an orthographic system of its own, also used for writing Sanskrit and Pali in Sri Lanka. Like most other South Asian systems it is alphasyllabic; that is, consonants imply an inherent vowel <a>, with other following vowels or the lack of one indicated by sattelite diacritics. The independent vowel symbols are used for word initial or independent vowels. Thus ප is <pa> and පා, පි, පු, පෙ, and පො, indicate <pa>, <pi>, <pu>, <pe>, and <po>, with (plain) <p> written as ප්. The full inventory, given in Table 2, does include symbols for aspirate consonants and others for writing Sanskrit and Pali as well as loans from those languages.

Morphology

Sinhala nouns inflect for definiteness, number, and case. The basic gender categories are animate and inanimate. Table 3 gives a partial set for Spoken and Literary. Literary Sinhala also distinguishes masculine and feminine within animate.

Spoken Sinhala has six cases, including the vocative: nominative, dative, genitive, instrumental-ablative, and vocative. Literary Sinhala and some dialects of Spoken also have a distinct accusative, though they differ in form.

Demonstratives and pronouns exhibit a four-way distinction: 1st proximal, 2nd proximal, distal, and (discourse) anaphoric. Thus, roughly, *me*: 'this by me', *oyə* 'that by you', *arə* 'that over there', and *e*: 'that has been spoken of'.

As stated earlier, Spoken Sinhala verbs lack person-number-gender agreement, while Literary Sinhala has it for all three categories. Both varieties have a number of forms for tense, mode, voice, and aspect, though the inventories differ somewhat. There is also a three-way derivational system with sets including active, causative, and involitive verbs, though some sets are incomplete. Thus, *kaḍənəwa* 'break' (active, transitive), *kaḍəwənəwa* 'cause (someone) to break', and *kæḍenəwa* 'get broken' (intransitive/involitive). The syntactic/semantic reflexes associated with these forms are complex and involve transitivity, causativity, and involitivity and the case of subjects and other grammatical relations, as well as special characteristics of specific

Table 2 The Sinhala writing system

Vowels					
අ	ආ	ඇ	ඈ	ඉ	ඊ
a	a:	æ	æ:	i	i:
උ	ඌ	ඍ	ඎ	ඏ	ඐ
u	u:	ṛ	ṛ:	ḷ	ḷ:
එ	ඒ	ඓ	ඔ	ඕ	ඖ
e	e:	ai	o	o:	au
Consonants					
ක	ඛ	ග	ඝ	ඞ	ඟ
ka	k^ha	ga	g^ha	ŋa	^{n}ga
च	ඡ	ජ	ඣ	ඤ	ඦ
ca	c^ha	ja	j^ha	ña	^{n}ja
ට	ඨ	ඩ	ඪ	ණ	ඬ
ṭa	$ṭ^h$a	ḍa	$ḍ^h$a	ṇa	^{n}ḍa
ප	ඵ	බ	භ	ම	ඹ
pa	p^ha	ba	b^ha	ma	^{m}ba
	ය	ර	ල	ව	
	ya	ra	la	va	
ශ	ෂ	ස	හ	ළ	
śa	ṣa	sa	ha	ḷa	

Other

The 'class nasal' ° (Si. *binduva*) is listed following the vowels, but usually represents a velar nasal, transcribed <ŋ> or <ṃ>.
A symbol ෆ has been introduced for <f>, but often Roman <f> is combined with ප <pa>, as in ෆ්.

Table 3 Spoken (colloquial) and literary nouns

	Singular[a]		*Plural*
	Definite	*Indefinite*	
Animate (masculine)			
Nominative/Direct			
Coll	miniha 'the man'	minihek	minissu
Lit	minisa:	minisek	minissu
Accusative			
Coll	minihawə	minihekwə	minissunwə
Lit	minisa:	minisaku (-eku)	minisun
Dative			
Coll	minihaṭə	minihekuṭə	minissunṭə
Lit	minisa:ṭa	minisakuṭa	minisunṭa
Inanimate			
Direct[b]			
Coll and Lit	potə 'the book'	potak	pot
Dative			
Coll and Lit	potəṭə	potakəṭə	potwələṭə/ potvələṭə

[a]Spoken forms are given in phonological representation; literary forms in transliteration.
[b]Nouns of this type have no separate accusative in either variety, but only a direct case serving both functions.

verbs. Thus the causative of *kiyənəwa* 'say, tell' is the common verb for 'read', but it is uncommon, though possible, in its causative sense, and its conjunctive participle *kiyəla* is also the quotation marker/complementizer in Spoken Sinhala (see (6) below).

Syntax

The basic word order in Sinhala is subject-object-verb, though other orders are not only possible but common for pragmatic effects such as foregrounding and emphasis. It is a thorough-going left-branching (i.e., right-headed) language, and verb and noun modifiers, including relative clauses, precede their heads. (The correlative relative construction generally characteristic of Indo-Aryan languages was lost early in its history.) It has postpositions, and complementizers are clause final. These characteristics are illustrated in (3) through (6).

(3) siri gunəpa:ləṭə potak dunna.
*Siri Gunapala-*DAT *book-*INDEF *give-*PAST
'Siri gave Gunapala a book.'

(4) mama ada koləm̆bə i^{n}dəla ko:ciyeŋ a:wa.
*I today Colombo-*GEN *from train-*INSTR *come-*PAST
'I came from Colombo by train today.'

(5) siri gunəpa:laṭə dunnə potə.
*Siri Gunapala-*DAT *give-*PAST-REL *book*
'The book that Siri gave Gunapala.'

(6) siri i:ye a:wa kiyəla gunəpa:lə kiwwa.
Siri yesterday came COMP *Gunapala say-*PAST
'Gunapala said that Siri came yesterday.'

Sinhala has the conjunctive participle that is a feature of both Indo-Aryan and Dravidian languages,

and it is the major way in which sentence conjunction is effected.

(7) siri kæ:mə ka:la gedərə giya.
*Siri food eat-*CONJPART *home went*
'Siri ate and went home.'

Nonverbal sentences, which are common, may be of numerous types, of which three are illustrated in (8) through (10). Such sentences do not have a copula, but vowel-ending adjective predicators take an assertion marker, as in (10).

(8) Nominal-equational:
me: potə puskolə potak.
*this book ola-leaf book-*INDEF
'This book is an ola-leaf manuscript.'

(9) Adjectival-attributive:
me: potə ho^{n}dayi.
*this book good-*ASSMKR
'This book is good.'

me: potə alut.
this book new
'This book is new.'

(10) Nonverbal modal:
maṭə e: alut navakəta:potə o:nə.
*I-*DAT *that new novel-book want/need*
'I want that new novel.'

Sinhala has the dative subject sentences common in South Asia. A nonverbal example was provided in (10). Dative subject verbal sentences commonly involve involitive verbs, as in (11):

(11) maṭə aliyek penuna.
*I-*DAT *elephant-*INDEF *see-*PAST
'I saw the elephant (it was visible to me).'

An uncommon feature of Sinhala is that it also has subjects in case forms other than nominative/direct and dative, in fact, in all except the genitive, as in (12)–(14). (12) illustrates the involitive optative verb inflection, indicating possibility of occurrence.

(12) minihawə ga^{n}gəṭə wæte:wi.
*man-*ACC *river-*DAT *fall-*INVOLOPT
'The man might fall into the river.'
(There are no accusative subject transitive sentences.)

(13) ehe: po:lisiyeŋ innəwa.
*there police-*INSTR *be (Animate)*
'There are police there.'

(14) a:nḍuweŋ e:kəṭə a:da:rə
*government-*INSTR *that-*DAT *support-*PL
denəwa.
*give-*PRES
'The government gives support for that.'

Sinhala has an interesting cleft or focused sentence construction that requires a special form of the verb, as in (15). The focused element may be virtually any type of sentence constituent, and it may be postposed as in (15) but need not be. This structure is very common in discourse and is used in most types of question word questions, as in (16). The question marker *də* that appears in (16) is also the way in which ordinary yes/no questions are formed, as in (17):

(15) i:ye gunəpa:ləṭə salli
*yesterday Gunapala-*DAT *money*
dunne e: miniha.
*give-*PAST-FOC *that man*
'It was that man who gave Gunapala money yesterday.'

(16) i:ye gunəpa:lə e: minih aṭə
*yesterday Gunapala that man-*DAT
dunne mokak də?
*give-*PAST-EMPH *what* Q
'What did Gunapala give that man yesterday?'

(17) e: miniha i:ye gunəpa:ləṭə
*that man yesterday Gunapala-*DAT
salli dunna də?
*money give-*PAST Q
'Did that man give Gunapala money yesterday?'

The related Dhivehi has a similar focus construction. It is also found in several Dravidian languages, and it is very likely that it, like other characteristics such as the completely left-branching nature of Sinhala-Dhivehi, is a result of language contact.

Sino-Tibetan Languages

R J LaPolla, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

The Sino-Tibetan (ST) language family includes the Sinitic languages (what for political reasons are known as Chinese 'dialects') and the 200 to 300 Tibeto-Burman (TB) languages. Geographically it stretches from Northeast India, Burma, Bangladesh, and northern Thailand in the southeast, throughout the Tibetan plateau to the north, across most of China and up to the Korean border in the northeast, and down to Taiwan and Hainan Island in the southeast. The family has come to be the way it is because of multiple migrations, often into areas where other languages were spoken (LaPolla, 2001). Proto-Sino-Tibetan (PST) would have been spoken in the Yellow River valley at least 6000 years ago. Waves of migration followed: to the southeast, forming the Sinitic languages, and to the west and southwest, forming the TB languages (the speakers of what became the Bodish languages migrated west into Tibet and then south, all the way to the Bay of Bengal, while the speakers of what became the rest of the TB languages followed the river valleys down along the eastern edge of the Tibetan plateau and across into Burma, India, and Nepal). The large spread of Mandarin Chinese to the northwest, southwest and northeast, giving it its large population and geographic spread, happened only in the last few hundred years.

In the past, and to some extent in China still today (e.g., Ma, 2003), this family was also said to include the Tai-Kadai (Zhuang-Dong) and Hmong-Mien (Miao-Yao) languages of southern China and Southeast Asia, but the resemblances found among Sinitic, Tai-Kadai, and Hmong-Mien are now understood to be a result of contact influence (these peoples originally inhabited southern China). Sino-Tibetan has the second largest number of speakers of any language family in the world, due largely to the over one billion Sinitic speakers; except for Burmese (see Bradley, 1996), most Tibeto-Burman languages have relatively few speakers.

Subgroupings within ST are still controversial, due to differences in criteria for subgrouping, a paucity of reliable data, particularly on morphosyntactic

Sino-Tibetan Languages

R J LaPolla, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

The Sino-Tibetan (ST) language family includes the Sinitic languages (what for political reasons are known as Chinese 'dialects') and the 200 to 300 Tibeto-Burman (TB) languages. Geographically it stretches from Northeast India, Burma, Bangladesh, and northern Thailand in the southeast, throughout the Tibetan plateau to the north, across most of China and up to the Korean border in the northeast, and down to Taiwan and Hainan Island in the southeast. The family has come to be the way it is because of multiple migrations, often into areas where other languages were spoken (LaPolla, 2001). Proto-Sino-Tibetan (PST) would have been spoken in the Yellow River valley at least 6000 years ago. Waves of migration followed: to the southeast, forming the Sinitic languages, and to the west and southwest, forming the TB languages (the speakers of what became the Bodish languages migrated west into Tibet and then south, all the way to the Bay of Bengal, while the speakers of what became the rest of the TB languages followed the river valleys down along the eastern edge of the Tibetan plateau and across into Burma, India, and Nepal). The large spread of Mandarin Chinese to the northwest, southwest and northeast, giving it its large population and geographic spread, happened only in the last few hundred years.

In the past, and to some extent in China still today (e.g., Ma, 2003), this family was also said to include the Tai-Kadai (Zhuang-Dong) and Hmong-Mien (Miao-Yao) languages of southern China and Southeast Asia, but the resemblances found among Sinitic, Tai-Kadai, and Hmong-Mien are now understood to be a result of contact influence (these peoples originally inhabited southern China). Sino-Tibetan has the second largest number of speakers of any language family in the world, due largely to the over one billion Sinitic speakers; except for Burmese (see Bradley, 1996), most Tibeto-Burman languages have relatively few speakers.

Subgroupings within ST are still controversial, due to differences in criteria for subgrouping, a paucity of reliable data, particularly on morphosyntactic

Figure 1 The subgrouping of Qiangic-Rung.

patterns, and the fact that the development and distribution of these languages has been greatly influenced by migration and language contact. Some of the influential proposals for subgrouping within TB are Grierson 1909, Shafer 1955, Benedict 1972, DeLancey 1987, Sun 1988, Dai, Liu & Fu 1989, Bradley 1997, Matisoff 2003, and Thurgood 2003 (see Hale 1982 for comparison of the older proposals). There is now general agreement on the existence of the following groupings (individual languages listed are only representative; see Matisoff 1996 for the many different names used for TB languages and groupings).

- Qiangic (Qiang, Pumi, Muya, Namuyi, Shixing);
- Lolo-Burmese, comprising the Burmish languages (Burmese, Lawngwaw [Maru], Ngo Chang [Achang], Zaiwa, Lachik [Lashi]) and the Loloish languages (further divided into Northern: Nosu [Yi, Yunnan or Sichuan], Nasu, Nisu; Central: Lahu, Lisu, Nusu, Jinuo; and Southern: Hani, Bisu, Phunoi, Mpi;
- Bodish (Tibetan, Dzongkha, Tamang (several varieties), Tshangla, Takpa);
- Kuki-Chin (Lushai, Asho Chin, Tiddim [Chin, Tedim], Anal, Hmar);
- Bodo-Koch (Bodo, Garo, Dimasa, Kachari, Koch, Rabha);
- Konyak (Tangsa [Naga, Tangsa], Chang [Naga, Chang], Konyak [Naga, Konyak], Nocte [Naga, Nocte], Wancho [Naga, Wancho]);
- Tani (Apatani, Mising [Miri], Adi); and
- Karenic (Pwo [Karen, Pwo], Karenni, Sgaw [Karen, S'gaw]).

There is much controversy over the affiliations of many of the languages of Northeast India and whether they all form a group together (see Burling, 1999; Matisoff, 1999), as well as the positions of the Bai language of Yunnan, China, Newari and the Kiranti languages of Nepal, Dulong-Rawang-Anong (Rawang) of Burma and China, the extinct Tangut language of northwest China, and the rGyalrong language of Sichuan, China, among many others. The latter two are most often said to be part of the Qiangic group, and the Kiranti languages are often seen as forming a higher grouping with the Bodish languages, but LaPolla (2003a), with reference to the morphological paradigms, argued that rGyalrong, the Kiranti languages (Bantawa, Athpare [Athapariya], Dumi, Khaling, Camling), Dulong-Rawang-Anong, the Kham languages, and the Western Himalayan languages (Kinnauri, Rongpo, Chaudangsi, Darmiya; also often grouped with Bodish) should be seen as forming a single higher-level grouping. This grouping was given the name 'Rung' because of the similarity (but not identity) of this proposal to an earlier one by Thurgood (1985). The Rung languages most likely split off from an even higher-level grouping with the Qiangic languages, then rGyalrong split off from the group as migrations moved south, then Western Himalayan split off from Kiranti and Rawang, and then these two groups split (**Figure 1**; see LaPolla, 2003a, for the evidence).

Within Sinitic, it is generally agreed there are at least six major dialect groups, initially distinguished on the basis of the reflexes of the historically voiced initial consonants (Li, 1936–1937): Mandarin (northern and southwestern China), Wu (Jiangsu and Zhejiang), Xiang (Hunan), Gan (Jiangxi), Yue (Guangdong and Guangxi), and Min (Guangdong, Fujian, Hainan Island, and Taiwan). The Hakka group of dialects (Guangdong, Fujian, Jiangxi, Sichuan, and Taiwan) is seen by some as part of the Gan group and by others as a separate group. Another three groups were proposed by Li (1987): the Jin group (Shanxi and Inner Mongolia), the Hui group (Anhui and Zhejiang), and the Pinghua group (Guangxi), but these groupings are not universally accepted. Norman (1988, 2003), based on a paradigmatic set of lexical and grammatical items, further grouped the dialect groups into the Northern (Mandarin) group, the Central group (some Xiang dialects, Wu, Gan), and the Southern group (Yue, Hakka, and some Xiang dialects). He left out the Min group because he felt that the Min dialects lay "outside the mainstream of Chinese linguistic development" (2003: 81). That is, they cannot be reconciled with the reconstructed Middle Chinese system (seventh century A.D.) to which the other dialect groups can be traced.

Mandarin has the largest geographic spread and population, and can be subdivided into as many as eight subgroups (see Li, 1987; cf. Ho, 2003), based largely on the reflexes of the stopped tone category. Of these, the Southwestern (Sichuan, Yunnan, Guizhou), Central Plains, and Jianghuai (Southeastern) groups are generally recognized.

One variety of Mandarin, *P≪ut – onghu\a,* the 'Common Language' of China today, was developed in the early 20th century (and dubbed *Gu|óy≪ŭ,* 'National Language,' at that time), taking the

phonology of the Beijing dialect but the lexicon and grammar from a more generalized Mandarin and from the vernacular literature of the time. Standardization and spread of the standard through aggressive educational programs continues today.

Min does not have a large spread and population, but because of the complex nature of its historical development (multiple migrations into the area, causing multiple strata, even within a single variety), it can be subdivided into as many as seven subgroups: Southern, Northern, Central, Eastern, Puxian, Shaojiang, and Qiongwen (Li, 1987). For an excellent book-length synchronic and historical overview of Sinitic, see Norman, 1988; for the best detailed analysis of a single dialect, see Chao (1968).

Proto-Sino-Tibetan was monosyllabic, but with a much more complicated syllable structure than most of the modern languages: *(PREF) (PREF) C_i (G) V (:) (C_f) (s) (Matisoff, 1991: 490; Ci = initial consonant, G = glide, : = vowel length, C_f = final consonant, s = suffixal *-*s;* parentheses mark items that do not appear in all syllables). The modern languages have moved much more toward bisyllabic or polysyllabic words, although they are often reduced again to sesquisyllabic (syllable and a half) or monosyllabic forms, and tone systems have developed in Sinitic and many of the TB languages (either through contact, through independent innovation, or a combination of the two). For example, in Sinitic the tones developed out of consonant suffixes (*-*s,* *-ʔ) and loss of initial voicing (Baxter, 1992: 8.2), and in Lhasa Tibetan the tones developed independently, out of loss of initial voicing and the influence of final consonants. Within this general commonality there is also diversity in phonemic inventories and syllable structures, with, for example, the Qiang language (LaPolla, 2003b) having 36 initial consonants, a complex system of consonant clusters in initial and final position, and no tones, while Lahu (Matisoff, 1973) has only 24 consonant initials, a simple (C)V syllable structure (no consonant clusters), and seven phonemic tones.

Proto-Sino-Tibetan morphology included derivational prefixes and suffixes and a voicing alternation of the initial consonant of some verbs that could affect the valency or form class of a word, but no relational morphology. Many of the modern languages have grammaticalized person-marking affixes on the verb and/or semantic role marking on nouns, but these cannot be reconstructed to the PST level (see LaPolla, 2003a, and references therein). The clause was verb focused, in that the verb was the key element, and noun phrases were optional. This is still the case in most languages. Most have not grammaticalized the kind of constraints on referent identification we associate with the concept of 'subject' and other grammatical relations. If noun phrases appeared in the clause, the verb would have been clause final. In Sinitic the clause is largely verb medial, as the verb has come to function as the divider between topical (preverbal) and nontopical (postverbal) elements (there has clearly been a progressive change away from verb-final order over time). This change has happened to a large extent in Bai and Karen as well. With morphology as with phonology we find diversity of types. Using our examples of Qiang and Lahu again, we find Qiang is agglutinative, whereas Lahu is isolating. Qiang has complex affixal systems of direction marking, person marking, and evidential marking on the verb and definite marking in noun phrases, whereas Lahu has none of these features. Both languages have developed complex sortal classifier systems – a common, but not universal, trait among ST languages. All ST languages have modifier-modified order in noun–noun structures (with genitive-head order being a subtype of this – there was no genitive marking in PST, but some languages have developed genitive marking), as well as relative-head order (Karen has a secondary head-relative order as well). Proto-Sino-Tibetan had negative-verb order, and this is still true of most ST languages.

Matisoff (2003) grouped the languages in the family into the 'Sinosphere' and the 'Indosphere' due to the linguistic and political influence of China and India, respectively, on the languages. In Indospheric languages, such as the TB languages of Northeast India and Nepal, for example, we often find the development of relative pronouns and corelative structures, and also of retroflex initial consonants. In the Sinosphere we often find the development of tone systems and more analytic structure. We also find contact influence from the Altaic languages in the north (Altaic speakers controlled large parts of northern China for long periods over the last thousand years) and the Austroasiatic, Tai-Kadai, and Hmong-Mien languages in the south. For example, there is a cline from north to south in terms of complexity of tone and also classifier systems (greater in the south, less in the north), and influence on prosody and word structure where the sesquisyllabic light-heavy structure of Austroasiatic languages is also found in many of the southern TB languages, such as Burmese and Jinghpaw (Jingpho), often leading to the reduction of the first syllable in a compound, in contrast to a trochaic stress pattern in northern TB and northern Sinitic, which often leads to the reduction of the second syllable in compounds.

Siouan Languages

R L Rankin, University of Kansas, Lawrence, KS, USA

© 2006 Elsevier Ltd. All rights reserved.

At the time of earliest contact with Europeans, the Siouan-speaking peoples were found in an arc extending from the northern high plains of North America, east and southward along the prairie-plains border to the mouth of the Arkansas River, with small enclaves farther to the east and southeast. The Siouan languages generally bear the names of the Native American tribes that speak them.

Subgroups, Locations, and Speaker Statistics

The Siouan languages fall into four major subgroups named after the river valleys where they were spoken in protohistoric times; however, the classification is based on shared linguistic innovations, not geography. Missouri River Siouan includes Crow, still spoken in southeastern Montana by perhaps 3000 persons of all ages, and Hidatsa in North Dakota, with approximately 60 speakers, all adults. Mississippi Valley Siouan is split into three major groups, Dakotan, Chiwere-Winnebago, and Dhegiha. Dakotan is spoken by over 10 000 persons of all ages in several dialects, including Assiniboine, Stoney, Teton, Yankton-Yanktonai, and Santee-Sisseton, scattered across northern Nebraska, Minnesota, the Dakotas, Montana, Manitoba, Saskatchewan, and Alberta. The Chiwere dialects are Ioway, Otoe, and Missouria, spoken originally in Iowa, southeastern Nebraska, and northern Missouri. The Missourias took refuge among the Otoes in 1829, and all three tribes were moved to Oklahoma by the 1880s, where today there are perhaps a very few elderly speakers. Winnebago, called Hochunk by its speakers and originally spoken in Wisconsin, is still spoken by adults both there and in Nebraska. The Dhegiha dialects are Omaha-Ponca, Kansa, Osage, and Quapaw. Omaha-Ponca is still spoken by perhaps 50 adults of both tribes in their ancestral home, Nebraska (Omaha), and near Ponca City, Oklahoma (Ponca). Kansa, also called Kaw, originally of northeastern Kansas; Osage, originally of southwestern Missouri; and Quapaw, originally of eastern Arkansas, now in northeastern Oklahoma, no longer have fluent native speakers.

Ohio Valley Siouan is extinct but once comprised several languages, Biloxi in southwestern Alabama, Ofo in Mississippi, and Tutelo-Saponi, Moniton, and Occaneechee in Virginia. There were a few Tutelo speakers living with the Cayuga in Ontario as recently as the early 1980s. The Mandan language, with only one or two speakers in North Dakota, is considered a separate subgroup by the author and a close relation of Mississippi Valley Siouan by some others. The Dakotan, Chiwere, and Dhegiha languages share a certain amount of mutual intelligibility subgroup internally, but there is little or no intelligibility among these subgroups or among other Siouan languages.

External Relationships

The Siouan family is related to the extinct Catawban languages of the Carolina Piedmont. These included Catawba and Woccon and a number of unattested languages said by explorers to have been similar. There is fairly strong recent evidence that Siouan-Catawban is related to Yuchi, originally spoken in Tennessee. Sapir (1929) proposed even more distant links to the Iroquoian and Caddoan language families, but there is little agreement among specialists on any of these.

Grammatical and Phonological Features

Siouan languages are primarily head-marking, active-stative, subject-object-verb (SOV), i.e., dependent-head languages of moderate morphological complexity. Sapir characterized Dakota Sioux as complex pure relational, with derivational concepts signaled by agglutinating elements and pure-relational (here, pronominal) concepts somewhat fused. Sapir characterized Dakota's overall morphological technique as agglutinative fusional and the degree of synthesis as synthetic to mildly polysynthetic. Siouan languages are among those considered by many linguists to be pronominal argument languages, i.e., the pronominal prefixes on the verb are considered to be the arguments of that verb, not just agreement markers for external arguments. If they are considered agreement markers, then Siouan languages are double-agreement languages, with prefixes for subject and object, or, alternatively, actor, patient/experiencer, along with additional roles such as recipient, locative, and instrumental. Siouan lexical classes include nouns, verbs, pronouns, postpositions, particles, and probably adverbs, but not adjectives. The equivalents of English adjectives are all conjugatable verbs.

Siouan argument structure is of the active-stative type in which the subjects of stative verbs (and some active verbs with experiencer subjects) and objects of active transitive verbs are marked alike, whereas agentive subjects of active verbs (both transitive and intransitive) are marked differently. Siouan

languages possess many of the other syntactic orderings that dependent-head languages tend to have (postpositions, main verb–auxiliary verb, possessor-noun (inalienable), and subordinate clause–main clause). All mark person, number, aspect (not tense), mode, and pronominal case in their verb morphologies, and permit noun incorporation. Nominal incorporation is most active in the northern languages: Crow may incorporate entire relative clauses within the verb. Many of the languages have fairly complex phonological inventories, including aspiration, glottalization, and nasalization contrasts for three or four places of articulation among consonants, and length contrasts for five oral and three nasal vowels. Many, if not most, Siouan languages have pitch accent and tend to assign accent to the second mora of words. Phonologists are warned that the practical orthographies, such as those developed by Riggs for Dakota or La Flesche for Omaha, lack detail necessary for phonological analysis.

Future Scholarship

Siouan scholarship is presently flourishing, but much remains to be done. New dictionaries are being or have recently been elaborated for Crow, Hidatsa, Mandan, Dakota, Chiwere, Winnebago, Kansa, Osage, and Quapaw, along with grammars of Crow, Hidatsa, Chiwere, Omaha, Osage, Biloxi, and Ofo. A comparative Siouan dictionary is nearing completion.

Situation Semantics

V Akman, Bilkent University, Ankara, Turkey

© 2006 Elsevier Ltd. All rights reserved.

Situation theory starts with a fundamental observation: reality consists of situations. A situation is a rich object consisting of individuals enjoying various properties and standing in a variety of relations. It is, in a sense, a 'small' world. We always find ourselves in situations. Right now, you, the reader, are in a reading situation. You are, I hope, satisfied with your being in this situation (notice that this is an attitude you have toward this situation). Some months ago, I, the author of this article, was in a writing situation (distributed over time and place).

Situations describe parts of the real world. Information flow is made possible by a network of abstract links between high-order uniformities, that is situation types. One of the distinguishing characteristics of situation theory *vis-à-vis* the traditional account is that information content is invariably context-dependent (Akman and Surav, 1997).

Situation semantics is applied situation theory. We are engaged in situation semantics if we are using situation-theoretic ideas – mathematical theories of information content – to study meaning in natural language. In fact, the two areas are not clearly separable, as the still-popular acronym STASS (situation theory and situation semantics) neatly shows.

Unlike the older and widely known approaches to natural language meaning (e.g., Montague grammar), there is certain natural feel to situation semantics. This makes it enticing for a newcomer to the realm of semantics. Situation semantics does not impose

languages possess many of the other syntactic orderings that dependent-head languages tend to have (postpositions, main verb–auxiliary verb, possessor-noun (inalienable), and subordinate clause–main clause). All mark person, number, aspect (not tense), mode, and pronominal case in their verb morphologies, and permit noun incorporation. Nominal incorporation is most active in the northern languages: Crow may incorporate entire relative clauses within the verb. Many of the languages have fairly complex phonological inventories, including aspiration, glottalization, and nasalization contrasts for three or four places of articulation among consonants, and length contrasts for five oral and three nasal vowels. Many, if not most, Siouan languages have pitch accent and tend to assign accent to the second mora of words. Phonologists are warned that the practical orthographies, such as those developed by Riggs for Dakota or La Flesche for Omaha, lack detail necessary for phonological analysis.

Future Scholarship

Siouan scholarship is presently flourishing, but much remains to be done. New dictionaries are being or have recently been elaborated for Crow, Hidatsa, Mandan, Dakota, Chiwere, Winnebago, Kansa, Osage, and Quapaw, along with grammars of Crow, Hidatsa, Chiwere, Omaha, Osage, Biloxi, and Ofo. A comparative Siouan dictionary is nearing completion.

Situation Semantics

V Akman, Bilkent University, Ankara, Turkey

© 2006 Elsevier Ltd. All rights reserved.

Situation theory starts with a fundamental observation: reality consists of situations. A situation is a rich object consisting of individuals enjoying various properties and standing in a variety of relations. It is, in a sense, a 'small' world. We always find ourselves in situations. Right now, you, the reader, are in a reading situation. You are, I hope, satisfied with your being in this situation (notice that this is an attitude you have toward this situation). Some months ago, I, the author of this article, was in a writing situation (distributed over time and place).

Situations describe parts of the real world. Information flow is made possible by a network of abstract links between high-order uniformities, that is situation types. One of the distinguishing characteristics of situation theory *vis-à-vis* the traditional account is that information content is invariably context-dependent (Akman and Surav, 1997).

Situation semantics is applied situation theory. We are engaged in situation semantics if we are using situation-theoretic ideas – mathematical theories of information content – to study meaning in natural language. In fact, the two areas are not clearly separable, as the still-popular acronym STASS (situation theory and situation semantics) neatly shows.

Unlike the older and widely known approaches to natural language meaning (e.g., Montague grammar), there is certain natural feel to situation semantics. This makes it enticing for a newcomer to the realm of semantics. Situation semantics does not impose

human-made assumptions in our conceptual scheme. It may be burdensome for someone to embrace, say, Montagovian intensions, but situations have a certain conceptual clarity and naturalness that make them believable. You may have heard that the classical model theory is a 'model' theory in the sense that it depicts how a logical theory should be like. Likewise, situation semantics is a fine exemplar of what a naturalized theory of semantics should be like.

Classical approaches to semantics underestimate the role played by context; they ignore factors such as intentions and circumstances of the individuals involved in the communicative process. (Or, rather, they place them in the pragmatics basket.) But, linguistic devices such as indexicals, demonstratives, and tenses rely heavily on context for interpretation and are fundamental to the way language carries information. Context-dependence is essential to situation semantics. (The insistence of situation semantics on contextual interpretation makes it compatible with speech act theory and discourse pragmatics.) A sentence can be used over and over again in different situations to say different things (called the efficiency of language). Its interpretation (i.e., the class of situations described by the sentence) is therefore subordinate to the situation in which the sentence is used. This context-providing situation (discourse situation) is the speech situation, including the speaker, the addressee, the time and place of the utterance, and the expression uttered. Because speakers are always in different situations, having different causal connections to the world and different information, the information conveyed by an utterance will be relative to its speaker and hearer (called the perspectival relativity of language).

Context supports not only facts about speakers, addressees, and so on, but also facts about the relations of discourse participants to other contextually relevant situations such as resource situations. Imagine two card games that are going on, one across town from the other. Suppose Alice is playing rummy with Bob and Carol is playing rummy with David. Elwood, watching the former card game, mistakes Alice for Carol, and mutters, *Carol has the ace of clubs*. According to the classical theory, if Carol indeed has the ace of clubs (A♣), his claim would be true since *Carol* and *the ace of clubs* are used to pick, among all the things in the world, the unique objects satisfying the properties of being someone named Carol and being an A♣, respectively. In contrast, situation semantics identifies these objects with respect to some limited situation – the resource situation exploited by Elwood. The claim would then be wrong even if Carol had the A♣ in the other card game.

In traditional semantics, statements that are true in the same models convey the same information. Situation semantics takes the view that logically equivalent sentences need not have the same subject matter because they need not describe situations involving the same objects and properties. The notion of partiality leads to a more fine-grained notion of information content and a stronger notion of logical consequence that does not lose track of the subject matter.

Ambiguity is another aspect of the efficiency of language. Natural language expressions may have more than one meaning. There are factors such as intonation, gesture, the place of an utterance, and so on that may play key roles in the interpretation of an utterance. Instead of downgrading ambiguity as an impurity of natural languages, situation semantics tries to build it into a full-fledged theory of linguistic meaning.

Intelligent agents generally make their way in the world by being able to pick up certain information from a situation, process it, and react accordingly. Being in a situation, such an agent has information about the situations he or she sees, hears about, believes in, and so on. Thus, upon hearing Bob's utterance *a wolf is running toward you*, Alice would have the information that her friend is the speaker and that he is addressing her with *you*. Moreover, by relying on the situation the utterance described, she would know that there is a wolf fast approaching her. She would then form a thought about this – an abstract object having the property of being a running wolf – and, on seeing the wolf around, her thought would start to correspond with facts. Normally, the realization of some type of situation causes an agent to acquire more information about that situation and to act accordingly. Alice would run away, having in her possession the acquired knowledge that wolves are hazardous. She activates this knowledge from the situation she finds herself in via a constraint – the link between wolves and their fame as life-threatening creatures. The role of constraints in information flow is best illustrated with an example. The statement *smoke means fire* expresses the lawlike relation that links situations in which there is smoke to situations in which there is a fire. If s is the type of smoky situations and f is the type of fire situations, then, by being attuned to the constraint $s \Rightarrow f$, an agent can pick up the information that there is a fire in a particular situation by observing that there is smoke.

Meaningful expressions are used to convey information not only about the external world but also about our minds (called the mental significance of language). Returning to an earlier example, consider the sentence *a wolf is running toward you* uttered by

Bob. It can give Alice information about two different situations. The first one is the situation that she is located in. The second one is Bob's mental (belief) situation. If Alice is certain that he is hallucinating, then she learns the second situation, not the first. Situation semantics differs from other approaches in that in attitude reports we do not describe our mind directly (by referring to states of mind, ideas, senses, thoughts, and whatnot) but indirectly (by referring to situations that are external).

According to situation semantics, the meanings of expressions reside in systematic relations between different types of situations. They can be identified with relations on discourse situations *d*, (speaker) connections *c*, the utterance situation *u* itself, and the described situation *e*. Some public facts about *u* – such as its speaker and time of utterance – are determined by the discourse situations. The ties of the mental states of the speaker and the hearer with the world constitute *c*.

A discourse situation *d* involves the expression uttered, its speaker, the spatiotemporal location of the utterance, and the addressee. Each of these defines a linguistic role (the role of the speaker, the role of the addressee, etc.). The utterance situation *u* constrains the world in a certain way, depending on how the roles for discourse situations, connections, and described situation are to be filled. For instance, an utterance *I am crying* defines a meaning relation:

d,c[[I am crying]]e

Given a discourse situation *d*, connections *c*, and a described situation *e*, this holds just in case there is a location *L* and a speaker *s* such that *s* is speaking at *L*, and, in *e*, *s* is crying at *L*.

In interpreting the utterance of an expression *f* in context, there is a flow of information, partly from the linguistic form encoded in *f* and partly from contextual factors provided by the utterance situation *u*. These are combined to form a set of constraints on the described situation *e*. This situation is not uniquely determined; there may be several situations that satisfy the constraints. The meaning of an utterance of *f* and hence its interpretation are influenced by other factors such as stress, modality, and intonation. However, the situation in which *f* is uttered and the situation *e* described by this utterance seem to play the most influential roles.

Guide to Literature

Ground-breaking work on STASS is due to the late Jon Barwise, well-known mathematical logician, and John Perry, prominent philosopher of language and mind. Barwise and Perry were the founders of Stanford University's Center for the Study of Language and Information (CSLI), which became almost synonymous with STASS research. In the beginning, the development of situation theory was hampered by a lack of appropriate tools. Later, the theory assembled its foundations based on innovations coming from set theory (Barwise and Etchemendy, 1987; Aczel, 1988). Barwise and Seligman (1997) further advanced the theory by introducing the concept of an information channel, which preserves information as it is transmitted through a system. Their work is in the spirit of Dretske's (1981) landmark work on information flow.

It is impossible to do justice to the profundity of STASS in a brief summary of this kind. The reader is referred to two seminal books, Barwise and Perry (1983) and Devlin (1991), for a thorough understanding. Although somewhat dated, the former is densely packed with excellent semantic common sense. The latter volume proposes a streamlined vocabulary and pays close attention to the foundations; it is the only modern introduction to STASS. (However, it does not render the Barwise and Perry volume obsolete; each book has its own merits.) Seligman and Moss (1997) is a beneficial survey that is mathematically demanding; it also has an excellent bibliography.

Various versions of situation theory have been applied to a number of linguistic issues (mainly) in English. The ideas emerging from research in situation semantics have also been coalesced with well-developed linguistic theories and have led to rigorous formalisms (Fenstad *et al.*, 1987). On the other hand, situation semantics has been compared to another influential approach to the theory of meaning, discourse representation theory (DRT).

Indexicals, demonstratives, referential uses of definite descriptions, deictic uses of pronouns, tense markers, and names all have technical treatments in situation semantics. Gawron and Peters (1990) focused on the semantics of pronominal anaphora and quantification. They argued that the ambiguities of sentences with pronouns can be resolved with an approach that represents anaphoric relations syntactically. They use a relational framework that considers anaphoric relations as relations between utterances in context. Cooper (1991, 1996) offered painstaking studies of linguistic problems to which situation semantics has been applied with some success. Tin and Akman (1994, 1996) showed how situation theory can be given a computational twist. They implemented a prefatory prototype (named BABY-SIT for obvious reasons) to program some practical problems, including anaphora resolution. Devlin and Rosenberg (1996) explored applications of situation

theory to the study of language use in everyday communication to improve human–computer interaction.

There used to be a specialized series of conferences devoted to recent developments in STASS. The first three volumes of proceedings were published as Cooper *et al.* (1990), Barwise *et al.* (1991), and Aczel *et al.* (1993). Nowadays, it is possible to find situation–theoretic papers dispersed in numerous conferences on logic, language, and information.

Finally, Devlin (2004) provides – despite the specific sounding title – a general appraisal of what STASS is all about; it may be consulted to get a better grasp of the historical developments that shaped STASS. Many of the Barwise papers reviewed by Devlin can be found in Barwise (1989), a fertile collection for technically oriented readers.

Skou Languages

M Donohue, National University of Singapore, Singapore

© 2006 Elsevier Ltd. All rights reserved.

The languages of the Skou family are spoken along the north coast of New Guinea, from the Skou villages east of Humboldt Bay in Indonesia to Barupu west of Aitape in Papua New Guinea. There are 16 known languages in the family, split fairly evenly between three family-level units and one isolate, I'saka (Krisa). Most of the languages are found along the coast, but the orientation of most groups lies inland. Tone and in most cases either unusual consonants or a high number of vowels feature prominently. Tonal contrasts range from three to six on a monosyllabic word, but in all well-investigated cases the domain of tone is the morpheme, not the syllable. Unusual segments found in the family include the palatal lateral dental affricate of Puare (Puari) and the nonback rounded vowels [ʉ] and [ø] of Skou. Contrastive nasalization on either the syllable or the rime is common. Other phonologically marked features include the lack of contrastive nasal consonants in I'saka and the lack of an /s/ phoneme in Skou or many of the Piore River languages.

Morphosyntactically the languages show a lot of variation from one to another, and only some salient features are mentioned here. The basic order is SOV, with postverbal obliques. Case marking is not used, but verbs typically show prefixal agreement for subject, and object agreement, if present, is suffixal. In the western group there is no suffixal agreement, but we do find alternations in the vowel of the verb root that indicate earlier affixation:

ke-fu
3.SING.NF-see.FEM.OBJ
'he saw her'

(where NF stands for nonfeminine) from earlier ke = fʉ-u. Compare this with Sumo, which has regular suffixation for object:

b-a-chara-u
MOOD-3.SING.MASC-see-3SING.FEM
'he saw her'

Often a language will employ one or more applicatives; typically a goal (beneficiary or direction) or, secondarily, an accompanier has dedicated applicative morphology, whereas instruments are not marked with applicatives but simply appear in the clause.

Many Skou languages show the frequent use of multiple exponence to mark the subject. In Puare we can see double marking for subject on the verb, once by an infix (marked here with angled brackets) and once by a proclitic, as in the sentence:

aro n-s<h>i
firewood 1.DU-chop<1.SING/DU>
'we chopped firewood'

Similarly in Skou we can find verbs with proclitic, prefix, and vowel agreement. The verb /ø/ 'shave' is [təri] when inflected for third-person plural

te-t-lø
3.PL-3.PL-shave<(3).PL>
'they shaved'

Gender is a pervasive feature of the languages. All the languages distinguish at least two genders in the third-person singular pronominal paradigms, and in most cases gender is found elsewhere as well. In Skou, all the dual pronouns, but none of the plural, are differentiated for gender. Barupu (Warupu) and Ramo both distinguish gender in all but the dual pronouns, both free and bound forms. The Serra Hills languages typically mark gender only in the second- and third-person dual pronouns. In Skou itself, a number of nouns obligatorily mark gender. Thus, *ʉme* 'woman' cannot appear on its own and must take the feminine clitic *pe, pe-ʉme* 'woman', and *ãku* 'child' is heard as *pe-ãku* 'girl' or *ke-ãku* 'boy'.

Slang Dictionaries, English

J Green, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The standard dictionary, the dominant production of lexicography, deals with standard forms of language. There are, however, a wide variety of nonstandard forms – regionalisms, jargon, technical terminology – which, while excluded from the standard lexica, require specific dictionaries. Of these the most common have been those of slang, a widely popular and continually evolving 'counterlanguage,' which has been collected for nearly half a millennium.

English slang lexicography falls into three periods: the 'canting' or criminal slang dictionaries of the 16th to the 18th centuries, the 'vulgar tongue' works of the late 18th to the mid-19th centuries, and the 'modern' productions that have appeared since.

Canting

The collection of 'cant,' properly the jargon of the mendicant criminal beggars of Tudor and Stuart England, echoes the near-contemporary 'beggar-books' of Europe: designed to alert the law-abiding public to the existence of such beggars – 'the canting crew' – listing their occupational types and offering a small glossary of their language. The first such work was Robert Copland's *The hye way to the Spytell House* (c. 1535). In the form of a verse dialogue between the printer Copland and the porter of the Spytell House (a charity hospital), Copland noted and the porter described the various categories of beggars and thieves, as well as their tricks and frauds. There is no glossary as such, but some 36 terms are defined in the text. Two similar and expanded works followed. In 1561 John Awdeley, another printer, published *The fraternitie of vagabondes*. The brief (nine-page) work, offering 48 headwords, falls into three parts: the first deals with rural villains, the second with their urban cousins, and the third is Awdeley's list of "the xxv. Orders of Knaues, otherwyse called a Quartern of Knaues."

The most influential 16th-century work appeared around 1566: Thomas Harman's *Caveat for common coursetours*. Harman, a magistrate, produced a consciously didactic work, designed to introduce the reader to "the leud lousey language of these lewtering [loitering] luskes [idlers] and lasy lorrels [blackguards] where with they bye and sell the common people as they pas through the country. Whych language they terme Peddelars Frenche ..." There are 24 small essays, each dealing with a different rank of villain, plus a list of some 114 terms. These are very briefly defined, usually with a single synonym. The *Caveat* concludes with a list of contemporary beggars and a cant dialogue.

Harman's vocabulary would remain the core of several subsequent glossaries, with a succession of 'rogue pamphlets' appearing over the two centuries. Among these are *The bellman of London* and *Lanthorne and candlelight* (1608) by the playwright Thomas Dekker, and *Martin Mark-All, beadle of Bridewell* by Samuel Rowlands (or Rid), in 1610. Others include Richard Head's *The canting academy*, or *The Devil's cabinet opened* (1673) and John Shirley's *Triumph of wit* (1688).

While Harman can be seen as a sociological researcher, and Dekker *et al.* as informative reformers, the 'coney-catching' pamphlets of playwright Robert Greene are nakedly sensational. The first such pamphlet, *A notable discouery of coosnage* [cozenage, or trickery]*: now daily practised by sundry lewd persons called Connie-Catchers* [confidence tricksters] *and Cross-biters* [swindlers] ... appeared in 1591. Five sequels followed by 1592. Greene gleefully peddled his downmarket sensationalism, larded with new canting terms – the vocabularies of the various branches of confidence trickery – and supposedly firsthand anecdote, but carefully quarantined with pious horror. In one pamphlet, *The defence of connycatching* 'by Cuthbert Conny-catcher,' he even attacked himself.

With *A new dictionary of the terms ancient and modern of the canting crew*, by the anonymous B.E., Gent.[leman] (c. 1698), there emerged the first major development in slang lexicography since Harman. It

Slang Dictionaries, English

J Green, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The standard dictionary, the dominant production of lexicography, deals with standard forms of language. There are, however, a wide variety of nonstandard forms – regionalisms, jargon, technical terminology – which, while excluded from the standard lexica, require specific dictionaries. Of these the most common have been those of slang, a widely popular and continually evolving 'counterlanguage,' which has been collected for nearly half a millennium.

English slang lexicography falls into three periods: the 'canting' or criminal slang dictionaries of the 16th to the 18th centuries, the 'vulgar tongue' works of the late 18th to the mid-19th centuries, and the 'modern' productions that have appeared since.

Canting

The collection of 'cant,' properly the jargon of the mendicant criminal beggars of Tudor and Stuart England, echoes the near-contemporary 'beggar-books' of Europe: designed to alert the law-abiding public to the existence of such beggars – 'the canting crew' – listing their occupational types and offering a small glossary of their language. The first such work was Robert Copland's *The hye way to the Spytell House* (c. 1535). In the form of a verse dialogue between the printer Copland and the porter of the Spytell House (a charity hospital), Copland noted and the porter described the various categories of beggars and thieves, as well as their tricks and frauds. There is no glossary as such, but some 36 terms are defined in the text. Two similar and expanded works followed. In 1561 John Awdeley, another printer, published *The fraternitie of vagabondes*. The brief (nine-page) work, offering 48 headwords, falls into three parts: the first deals with rural villains, the second with their urban cousins, and the third is Awdeley's list of "the xxv. Orders of Knaues, otherwyse called a Quartern of Knaues."

The most influential 16th-century work appeared around 1566: Thomas Harman's *Caveat for common coursetours*. Harman, a magistrate, produced a consciously didactic work, designed to introduce the reader to "the leud lousey language of these lewtering [loitering] luskes [idlers] and lasy lorrels [blackguards] where with they bye and sell the common people as they pas through the country. Whych language they terme Peddelars Frenche ..." There are 24 small essays, each dealing with a different rank of villain, plus a list of some 114 terms. These are very briefly defined, usually with a single synonym. The *Caveat* concludes with a list of contemporary beggars and a cant dialogue.

Harman's vocabulary would remain the core of several subsequent glossaries, with a succession of 'rogue pamphlets' appearing over the two centuries. Among these are *The bellman of London* and *Lanthorne and candlelight* (1608) by the playwright Thomas Dekker, and *Martin Mark-All, beadle of Bridewell* by Samuel Rowlands (or Rid), in 1610. Others include Richard Head's *The canting academy*, or *The Devil's cabinet opened* (1673) and John Shirley's *Triumph of wit* (1688).

While Harman can be seen as a sociological researcher, and Dekker *et al.* as informative reformers, the 'coney-catching' pamphlets of playwright Robert Greene are nakedly sensational. The first such pamphlet, *A notable discouery of coosnage* [cozenage, or trickery]*: now daily practised by sundry lewd persons called Connie-Catchers* [confidence tricksters] *and Cross-biters* [swindlers] ... appeared in 1591. Five sequels followed by 1592. Greene gleefully peddled his downmarket sensationalism, larded with new canting terms – the vocabularies of the various branches of confidence trickery – and supposedly firsthand anecdote, but carefully quarantined with pious horror. In one pamphlet, *The defence of connycatching* 'by Cuthbert Conny-catcher,' he even attacked himself.

With *A new dictionary of the terms ancient and modern of the canting crew*, by the anonymous B.E., Gent.[leman] (c. 1698), there emerged the first major development in slang lexicography since Harman. It

is the first ever stand-alone 'slang dictionary,' rather than an appended glossary. The title emphasizes canting but B.E.'s vocabulary, some 4000 words, adds general slang, colloquialisms, and a variety of noncriminal jargons to the core material. There are other innovations: for some entries, however few, he offered citations and etymologies, there are a number of crossreferences, and he adopted usage labels.

Like Harman, B.E. would be 'honored' by his plagiarists. These included Captain Alexander Smith, whose *Thieves' new canting dictionary*, in his history of highwaymen (1719), is unashamedly derivative. Similarly the *New canting dictionary* (1725) is no more than an adaptation. The glossary attached to the oft-reprinted *Life* of the self-styled gypsy king Bamfylde Moore Carew (1750 *et seq.*) is similarly sourced. And it is B.E. whose word list provided the basis of the 'Collection of canting words' included in Bailey's *Universal etymological English dictionary* (1737).

The Vulgar Tongue

The 18th century did not merely produce adaptations of B.E. Among other works, all offering glossaries, are *Hell upon Earth* (1703), *The memoirs of the right villainous John Hall* (1708), *The amorous gallant's tongue*, by 'G.L.' (1710 *et seq.*), *The regulator* (1718) by Claude Hitchens, Daniel Defoe's *Street robberies considered* (1728), James Dalton's *Genuine narrative of street robberies considered* (1728), the confessional *Discoveries of John Poulter* (1753), and George Parker's *View of society in high and low life* (1781) and *Life's painter of variegated characters* (1789).

In 1785 arrived the next way station in slang collection: *A classical dictionary of the vulgar tongue*, by the antiquary and former militia officer Captain Francis Grose. A second, substantially augmented edition appeared in 1788, followed by a third in 1796, the pirated *Lexicon Balatronicum* (effectively the fourth) in 1811, and the fifth, edited by the boxing journalist Pierce Egan, in 1823. In his 4000 headwords Grose incorporated his main predecessors, but expanded much further into general slang, his 'vulgar tongue.' Grose now set the pattern for the next century. One other dictionary appeared in 1823, that 'of the turf, the ring, the chase, the pit, of bon ton and the varieties of life' Its author was 'Jon Bee' (properly John Badcock), who had already challenged Egan's bestselling chronicle of *Life in London* (1821) with his own hugely derivative *Real life in London* (1821). Badcock's book is far more verbose than Egan's, but lexicographically it is more curiosity than a linguistic tool.

Four more noteworthy dictionaries appeared before 1900. The first, in 1857, was the brief *Vulgar tongue* by 'Ducange Anglicanus.' It comprises a pair of glossaries, the first collected by the author, the second from a report presented to the Government in 1839. In addition there is 'The leary man,' a flash song, and a tailor's handbill written in slang, with a translation into standard English on the reverse. It is the first to offer rhyming slang. In 1859 appeared the first of the six editions (variously expanded) of John Camden Hotten's *Modern slang, cant and vulgar words*, latterly *The slang dictionary*. Hotten was variously a bookseller/publisher, a pirate of such American 'stars' as Mark Twain, and a cultivator of his 'flower garden,' books of flagellant pornography. The dictionary has lists of rhyming slang and of back slang, both prefaced by a brief history and discussion. There is, for the first time, a 'bibliography of slang and cant,' listing some 120 titles, plus his own critical comments on each. Hotten stressed that this is above all a dictionary of "**modern** Slang – a list of colloquial words and phrases in **present** use – whether of ancient or modern formation." He omitted obsolete terms and opted, unlike Grose, to exclude 'filthy and obscene words' although he acknowledged their prevalence in street talk. He touched on jargon, without describing it as such, and thus dealt with the terminology of the *beau monde*, politics, the army and navy, the church, the law, literature, and the theater. He had a list of slang terms for money, one of oaths, and one for drunkenness and dealt with the language of shopkeepers and workmen.

Hotten was **the** slang dictionary until 1890. His pre-eminence was somewhat breached in 1889 by *The dictionary of slang, jargon and cant* by Albert Barrère and C. G. Leland. But this two-volume work had barely been published when it was displaced, by the seven volumes of John Farmer and W. E. Henley's *Slang and its analogues* (1890–1904). Farmer, who combined slang researches with writings on spiritualism, and Henley, then one of Britain's leading poets, took slang lexicography into a new dimension (subsequently renamed the *Oxford English dictionary*; see **English Lexicography**). The book adopted the same 'historical' method as the contemporaneous *New English dictionary*. All but a few headwords come with a number of citations, some 100 000 in all, set out as in a standard English dictionary, to illustrate usage and nuance. These quotes take in "the whole period of English literature from the earliest down to the present time" and are arranged as far as possible from 'first use' to current use. As well as citations there are wherever possible foreign synonyms for the slang. English synonymy is also paramount: those listed at *monosyllable* (i.e., *cunt*), for instance, run to 13 columns, while those at *greens* (sexual intercourse) run to seven. There are errors, typically in the citations,

where dates and even the quotes themselves may have fallen foul of the sheer size of the undertaking, but the overall achievement of Farmer and Henley far outweighs such slips.

Modernity

To list the collections of 20th- and 21st-century slang is impossible. The range, from massively researched multivolume 'historical' dictionaries, to fly-by-night glossaries posted on the Internet, defies cataloging. Nor is it possible to restrict 'English' slang to England. While the last slang lexicographer to dominate his field, Eric Partridge, could entitle his book, based originally on Farmer and Henley, whose rights were owned by his publisher, as the *Dictionary of slang and unconventional English* (*DSUE*) (1937–1984) and focus almost exclusively on the language of England, such exclusivity would now be foolhardy. In dictionaries as in the vocabulary, American slang has taken over, and must take equal prominence. Similarly Australian slang, pioneered by the mid-20th century work of Sidney J. Baker, has an important presence. The mass media, the Internet, and the role of English, or rather **Englishes**, as a world language mean that its slang is equally multiheaded and its dictionaries reflect that fact.

Partridge, as mentioned, dominated much of the 20th century. His is perhaps a flawed canon: his lexicographical method was less than wholly scrupulous, his inability to keep personal comment out of his definitions less than useful, his etymologizing sometimes tendentious, but his body of work can be said to have maintained the momentum of slang lexicography through the mid-20th century. He has that rare accolade: like Webster, his name became an eponym. The last edition of the *DSUE* appeared in 1984; an Americanized edition, from 1945 onwards, will appear in 2005 edited by Tom Dalzell. Partridge's immediate successor, Jonathon Green, published his single-volume *Cassell Dictionary of Slang* in 1998; a multivolume 'historical' expansion is due in 2007.

America

Slang is an urban phenomenon. Modern America seems quintessentially urban; 19th-century America was not. Thus the century saw only one major slang dictionary: the *Vocabulum* by the New York chief of police, G. W. Matsell (1859). Its only predecessor is a short glossary appended by Edward Judson to his *Mysteries and miseries of New York* (1848). Much of his vocabulary seems to have been taken wholesale from Egan's revision of Grose, although there are a number of genuine localisms. Nonetheless, there were no contenders: Matsell remains an American pioneer.

The 20th century hosted an explosion of US slang lexica. Many of these, such as Jackson and Hellyer's *Vocabulary of criminal slang* (1914), Godfrey Irwin's *American tramp and underworld slang* (1931), Hyman E Goldin's *Dictionary of American underworld lingo* (1950), or the wide-ranging specialist work of David Maurer, published in *American Speech* and elsewhere, point up the wide variety of US criminal slang. More general works include Maurice H. Weseen's *Dictionary of American slang* (1934), Lester V. Berrey and Melvin Van der Bark's *American thesaurus of slang* (1942, 1952), Harold Wentworth and Stuart Berg Flexner's *Dictionary of American slang* (1960, 1975), and, pre-eminently, Jonathan Lighter's multivolume work in progress, *The historical dictionary of American slang* (1994–). Specialist works abound, especially as regards such sources of slang as the campus, African-American speech, drugs and war. Among these are Connie Eble's series of *Campus slang* glossaries (1972–) and the works of Edith A Folb (*Runnin' down some lines*, 1980), Geneva Smitherman (*Black talk*, 1994), Richard A. Spears (*The slang and jargon of drugs and drink*, 1986), and Gregory C. Clark (*Words of the Vietnam War*, 1990).

Today's anglophone slang is international rather than parochially English. And its sources, including dictionaries, are increasingly so as the Internet gains influence and online reference searches replace the traditional printed works. The upcoming crop of multivolume lexica may signify the end of a half-millennium era. 'Slang dictionary' obtains 75 000 hits on Google: slang collection, one might suggest, has barely begun.

Slang, Argot and Ingroup Codes

C Eble, University of North Carolina, Chapel Hill, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

Slang, argot, and ingroup codes are sets of words and expressions that are motivated by the social and interpersonal functions of language. Their purpose is to bring about a social bond among their users through awareness of shared knowledge. Such vocabulary is usually an alternative to words and expressions in the standard variety of the language. For example, many topics that American college students talk about are time-honored on college campuses and can be referred to with general vocabulary. For social reasons, though, at the beginning of the 21st century American students used *bia* for 'a thoroughly unpleasant female,' *pimp* for 'a popular male,' and *money* for 'very good,' as in "Last night's concert was money."

By comparison with the general vocabulary, such socially salient words and expressions are often short-lived and fall into disuse quickly by being displaced by

new synonyms. In 2004, American teenagers showed themselves attuned to hip-hop culture by using the slang word *bangin'* to describe anything overwhelmingly positive, as in "Last night's concert was *bangin.*" Their parents in the 1970s would have said *awesome*, and their grandparents a generation earlier would have said *swell* to show that they were part of the group in-the-know in their youth. A comparison between the slang used by college students at the same American university at two points 30 years apart showed that 95% of the items submitted as good, current campus slang in 1974 were not submitted in 2004. Although the actual words were almost entirely different at the two points, the topics were highly congruent. The same meanings – positive and negative evaluations, alcohol and drugs and their use, dress and grooming, and so forth – accounted for about three-fourths of the items in each year (Eble, 2005: 3).

Slang, argot, and ingroup code are not technical terms with precise definitions. Slang, the most general and widely used of the three, refers to an ever-changing set of words and phrases that speakers use in casual conversation but usually avoid when writing or when interacting with strangers or on important occasions. The purpose of slang is to establish or reinforce social identity or cohesiveness, either within a group or with a trend or fashion in society at large. Robert Chapman distinguishes two types of slang based on its group delimiting function. Primary slang is "the pristine speech of subculture members" (Chapman, 1986: xii). Secondary slang is "a matter of stylistic choice rather than true identification" (Chapman, 1986: xii). Almost everyone who interacts informally with others uses secondary slang, be it as ordinary and enduring as current American *bomb* 'fail miserably,' *hit the hay* 'go to bed,' and *poop out* 'quit'; or as flashy as *bling bling* 'jewelry,' borrowed from hip-hop culture; or as cosmopolitan as *metrosexual* 'a fashion-conscious heterosexual male,' in vogue in 2003.

Social groups are fertile breeding grounds for primary slang – a self-conscious, irreverent, and often clever vocabulary to enhance solidarity among members and to set them apart from those outside the group. Often the slang vocabulary that such groups create refers to the activity or behavior that is the basis for their association. Surfers, for instance, have developed many ways to refer to ocean waves and to their equipment. They call 'the hollow part of a wave' a *tube* or a *barrel* and 'a surfboard for big waves' a *big gun*. Skateboarders call the small injuries of their sport *bongos* or *road rash*. Military aviators use *bingo* for 'the minimum amount of fuel for a safe return to base,' *music* for 'electronic jamming to deceive radar,' and *nylon letdown* for 'ejection followed by a parachute ride.' The primary slang of groups sometimes diffuses into the informal registers of the general population, for example *foul up* 'fail through confusion or ineptitude' and *zap* 'kill, put an end to' from military slang. During the last decades of the 20th century, the slang of African Americans gained widespread recognition and adoption in common parlance, contributing *bad* 'good,' *chill out* 'relax,' *homeboy/homegirl* 'friend,' and many more.

Secondary slang signals identification with a style or attitude rather than with a specific, easily delineated group. English *coffin nail* 'cigarette,' *freebie* 'article or service given for free,' *sack* 'discharge from employment,' and *loaded* 'drunk' are all labeled *slang* in one current American desk dictionary. Yet none of these terms marks a speaker as belonging to a group. The use of slang items like these conveys an attitude of nonchalance, flippancy, or irreverence. For a smoker to call a 'cigarette' a *coffin nail*, for example, suggests defiance of the known relationship between smoking tobacco and fatal disease. Describing an intoxicated person as *loaded, polluted*, *torn out of the frame, wasted*, and the like pictures the intemperate drinker as a victim rather than an agent of behavior potentially harmful to the individual or to society.

Argot is the distinctive vocabulary developed by a group. Argot differs from primary slang only because historically the terms *argot* and *cant* usually applied to groups that operate on the periphery of respectable society, such as con artists, thieves, or, more recently, drug dealers. Their argot is often held in secret and deliberately separates them and their activities from outsiders. At the extreme, the argot of a group that is completely alienated from society, such as prison inmates, can develop into an *antilanguage* (Halliday, 1976). Personal websites on the internet show that many players of alternative reality games understand the function of antilanguage in opposing the established order and create vocabulary for their imagined antisociety. Players of the role-playing game 'Shadowrun' (a registered trademark of Fantasy Productions) form a worldwide community via the internet. One site maintains a 'Shadowslang Glossary.' *The Shadows* is a 'quasi-criminal world,' and a *shadowrun* is 'any movement, action, or series of such made in carrying out plans which are illegal or quasi-legal.' An example of *Shadowslang* is *sidewalk outline* for 'a recently deceased person,' an allusion to the chalk outline of a body at a murder scene. 'Shadowrun' vocabulary is evolving and open-ended, and players submit new vocabulary to the list.

Ingroup code usually refers to deliberate and collaborative lexical inventions or systematic alterations of the standard language, sometimes involving only two or three people. For English, the widely known pig latin is an ingroup code, though the ingroup

includes virtually every school child. More typically, ingroup codes are shared by twins, siblings, or an intimate set of friends and seldom exert influence beyond the small circle of users. Like pig latin, ingroup codes may involve deviating systematically from the standard patterns of word and sentence structure.

By form, slang, argot, and ingroup code are not distinguishable from the general vocabulary of a language. Ordinary word-building processes apply. In English, slang arises from compounding (*freeload* 'take advantage of the generosity of others'); affixation (*megabucks* 'lots of money'; *spacey* 'unaware'); shortening (*abs* 'abdominal muscles'); blending (*vomatose* 'disgusting,' from *vomit* + *comatose)*; acronymy (*snafu* 'malfunction,' from *situation normal all fucked up*; *o.d.*, from *over dose*); and shifts in grammatical function (*creep* 'unpleasant person,' from verb to noun). The semantic processes favored are those that rely on shared knowledge: metaphor (*porcelain god* 'toilet'), metonymy (*ice* 'diamonds'), and allusion (*oreo* 'black person with white values,' from *Oreo*, trademark for a chocolate cookie with a cream filling).

The range of meaning evoked by slang, argot, and ingroup codes is narrow, tending to refer to types of people, personal relationships, and judgments of acceptance or rejection. Because these types of vocabulary arise in opposition to a general norm, their tone tends to be negative, and they elaborate on the taboos of the dominant culture. As a result, these kinds of words and expressions are often tasteless or offensive – expressing images of sex, violence, and bigotry. For instance, synonyms for sexual organs include *heat seeking missile* for 'penis,' *snapping turtle* for 'vagina,' and *knockers* for 'woman's breasts.' The hundreds of synonyms for 'sexual intercourse' include *bounce refrigerators, bumping uglies, laying pipe, knocking boots*, and *slamming;* and a 'sexual partner' is a *slampiece*. 'Caucasians' are *honkies*, 'Arabs' are *camel jockies*, and 'Asians' are *gooks*. 'Incompetent or unlikable people' are *assholes, dickheads*, and *pricks*.

Technological advances in communication have added new dimensions to vocabulary whose purpose is social rather than ideational. From the earliest observations centuries ago, slang and argot were characterized as primarily oral and linked to subcultures within a society. Slang is now transmitted in writing and across linguistic and cultural boundaries by websites, electronic chat rooms, and email. A kind of e-mail slang marks users in-the-know. Predictable emotions and reactions are often represented by an evolving set of shortenings and acronyms, for instance LOL 'laughing out loud' or OMG 'o, my God.' Iconic representations of emotions made at first with key strokes are now a standard feature of word processing graphics, for example ☺ 'smiley face.' Such emoticons are so widespread that they carry no nuance of irreverence or of in-group knowledge and are now more equivalent to informal oral usage than to slang.

The groups that create and maintain slang are now more amorphous and open, and many form deliberately around a common interest rather than on the basis of physical and social proximity. One such group is united by cult-like devotion to the television series *Buffy the Vampire Slayer*, which ran for seven seasons, 1997–2003. Its distinctive vocabulary was invented by the writers of the drama and promulgated and elaborated on by *Buffy* fans. Buffyisms are posted on websites, exchanged in e-mail messages, and printed in magazines and books. Linguist Michael Adams offers an insightful analysis of the recently possible linguistic phenomenon in *Slayer Slang* (Adams, 2003). An even less coherent group is constituted by the followers of hip-hop culture and rap music. The fashion value of the style invented by African American youth in urban ghettos has given international cachet to hip-hop slang such as *dawg, floss, holla back, pimp*, *playa, props*, and *word*. Thanks to new means of communication, youth around the world who have never met or spoken to an African American jockey for social status among their peers by using the slang popularized by hip-hop.

Another new dimension to slang and similar kinds of vocabulary is instantaneous diffusion. Live television carries news events and entertainment to distant locations 24 hours a day. Socially salient vocabulary that is created for a film or a television series, a comedy routine, or the lyrics of a song need not spread from one speaker to another by personal communication. An appealing turn-of-phrase can be uttered in a film or on a television program in California one night and be spoken the next day in Munich or Beijing.

There is no evidence that written, widespread, and instant diffusion of slang has diminished the long recognized effects of its use.

Slavic Languages

L A Janda, University of North Carolina, Chapel Hill, NC, USA

The Slavic language group contains three subfamilies: (1) East Slavic, consisting of Russian, Belarusian (Belarusan), and Ukrainian; (2) West Slavic, consisting of Polish, Czech, Slovak, and Sorbian (the latter spoken in Germany and also known as Lusatian); and (3) South Slavic, consisting of Bulgarian, Macedonian, Slovene (Slovenian), and Bosnian/Croatian/Serbian (BCS; formerly known as Serbo-Croatian). The Slavs are believed to have expanded from an area corresponding to southwestern Belarus/northwestern Ukraine beginning in the 6th century C.E., an event that contributed to the linguistic differentiation of Late Common Slavic (LCS) into the modern Slavic languages. In the late 9th century a Byzantine mission to the present-day eastern Czech Republic yielded translations of liturgical texts into Old Church Slav(on)ic, a written language presumed to be very close to LCS. These documents have made it possible for us to reconstruct the history of the Slavic languages quite reliably. Orthography follows religion in dividing the Slavic languages into an Eastern/Orthodox Christian group that uses the Cyrillic alphabet (Russian, Belarusian, Ukrainian, Bulgarian, Macedonian, and part of BCS), and a Western/Catholic and Protestant group that uses the Latin alphabet with the addition of diacritics (Polish, Czech, Slovak, Sorbian, Slovene, and part of BCS).

Phonological History

Within the Indo-European language family, the closest relatives to the Slavic languages are the Baltic languages (Latvian and Lithuanian). Both Slavic and Baltic are 'satem' languages, a name based on the Avestan word for 'hundred,' which identifies the reflex of Proto-Indo-European (PIE) *k'* → *s* (and *g'* → *z*), as in the Late Common Slavic (LCS) *sъto* 'hundred'. Peculiar to Slavic (though with some analogues in Baltic and Indo-Iranian languages) is the 'ruki' rule sound change, which caused *s* (*š*) → *x* in positions following *r*, *u*, *k*/*g*, and *i*, as in Proto-Indo-European (PIE) *ousos* → LCS *uxo* 'ear'. 'Ruki' and 'satem' are ancient changes in the development of PIE into Early Proto-Slavic (EPSl). The subsequent era linking EPSl and LCS is marked by sound changes that affected all of Slavic, though their ultimate outcomes are not entirely uniform. Many EPSl-to-LCS sound changes reflect a phonotactic strategy aimed at creating 'ideal' syllables of rising sonority and level tonality, i.e., syllables with CV structure where both the C and V elements had the same (high or low) tonality (also known as 'syllabic synharmony'). The conflict between the most normal structure for a root morpheme, which was CVC, and the ideal syllable structure of CV resulted in the great number of morphophonemic alternations so characteristic of Slavic. The last element in a CVC sequence was in a precarious position: either it was assigned to the syllable containing the preceding CV, in which case sonority constraints made it subject to absorption or loss, or it

Introduction

It is with frustration and a nice sense of humor that William Labov advises that all articles on slang should be consigned to "an outer, extra-linguistic darkness" (Labov, 1972: 97), but linguists do not have that privilege. In defining slang, one needs to remember four vital aspects: firstly, slang is typical of the spoken, colloquial, informal aspects of human interaction, and its presence will markedly lower the dignity of formal or serious speech or writing since it is not generally accepted in standard educated speech. Secondly, typically such words are restricted in their social status and distribution, and they are more metaphorical and transitory than standard language, rapidly going in and out of fashion within the particular subculture that knows and uses them. For example, the word *groovy*, so popular in the 1960s, has long since lost its appeal and has been replaced by other, more trendy equivalents of *nice*, such as *blind*, *epic*, and *legend*. A third feature of slang is the fact that it is generally vague in meaning, and slang words are notoriously difficult to define. This is partly because slang is primarily verbal, and seldom finds its way into print, which means that the spellings for slang words tend to be idiosyncratic and problematic. A further reason why most slang terms are etymologically obscure is the fact that they are coined off-the-cuff, in oral discourse: speakers hear them and subsequently use them without being sure of their meanings, which resultantly distort, shift, and adjust over time. Also, many slang words refer to taboo aspects of life, where secrecy is important.

Not only is slang restricted in terms of its 'shelf-life,' so to speak, but it is also typically localized, both geographically and socially, and will only be recognized in certain areas or institutions, where people are in regular and close contact with each other, such as schools, prisons, army camps, and the like. Thus, anyone seeking to make generalizations about slang faces the inevitable problem that such linguistic usage is inherently colored by the social, cultural, geographical, and temporal context of users. There is no single set of English slang words, obviously, because of its localized and topical nature, and the fact that it flourishes in small and intimate subcultures. While broad trends and truisms are evident across languages, this entry draws examples from South African English teenagers elicited between 1990 and 2003.

The Social Functions of Slang

Membership of the Group

The main use of slang is to show that one belongs to a particular subculture and that one is on the same wave-length as they are. For this reason, slang thrives where group membership and solidarity are important. These words act as badges of membership, and are used in much the same way as fashions in clothing and hairstyles are used. By using the slang of the group with whom one associates oneself (or wishes to associate oneself), one is sporting a symbol of a sort.

Slang is typical of any tight-knit linguistic community where a relaxed atmosphere among peers or people of equal status provides a space where language is liberated from the conventions and pretensions of politeness and formality that govern the ideal standards for language use in society. Thus, slang may be found among factory workers, sailors, and miners, for example, and the more isolated a particular social group is from mass social intercommunication, the higher the likelihood that group has for using language that deviates from formal standard language use. For this reason, slang is often found among younger generations of people, especially adolescents. This is because adolescence is a time of life when belonging is of particular importance, and when age cohorts find themselves constantly in each others' company for educational, sporting, and entertainment purposes. For adolescents, slang forms part of a shared linguistic code, reinforcing group membership, indicative of shared knowledge and interests and the all-important sense of belonging (Hudson, 1983; Munro, 1989). As Crystal puts it, "the chief use of slang is to show that you're one of the gang" (Crystal, 1987: 53).

To further complicate matters, using slang does not necessarily imply that one knows the meaning of these words. Because slang is used on informal occasions among peers with a high degree of shared knowledge and common interests, it forms part of a contextualized restricted code, full of highly implicit connotations. New 'wannabe' members of a particular group or subculture would typically pick up the slang by careful observation. Asking about the meaning of such words would be like admitting failure as a prospective member of the group. In any event it is unlikely that anyone would be able to explain their slang terms' real and complete meaning

to an outsider, since the main reason for their very existence lies in their connotations (Sornig, 1981: 1). For this reason, many slang users have only a very vague idea of what their slang words mean. The very essence of such words rests in their vagueness and adaptability. As Hall (2002) points out, *cool* can be used to describe a teacher (popular), a shirt (fashionable), a test (easy) or a potential problem (inconsequential). It generally connotes the fashionable or the approved, and includes an easy-going, laid-back attitude. Similarly, the exact meanings of verbs like *suck* (with negative connotations), *rock* (with positive connotations!), and adjectives such as *hectic* (used to describe anything from a difficult lecture, or a terrible car crash to an enjoyable meal), are all equally elusive.

Creativity, Fun, and Fashion

One of the more positive functions of slang is its witty and humorous effect, often with a touch of creativity, driven by the constant desire to be innovative and create a rhetorical effect, such as incongruity, irreverence, or exaggeration. In this role, slang is used to oil the cogs of socialization, to reduce seriousness, poke fun and to be witty and clever, and many of these words are flippant, irreverent and lightheartedly indecorous. Slang constantly reveals considerable delight in the language as an expressive, almost poetic, medium, evidenced by the amount of rhyme, alliteration, metaphor, onomatopoeia, and other linguistic devices it draws on, for example, *blow some zeds* (sleep), *act like jeans and fade* (go away), *ruggerbugger* (macho young man).

The evanescence of slang gives it a trendy or fashionable feel that makes those who use it feel 'cool.' In the words of Hall (2002), who discusses the expressions *crashing* (staying over), and *hanging* (staying at home; doing nothing), "It'd be risky to dwell on the words ... they may have undergone some permutations since I heard them a few hours ago." This up-do-date-ness of slang means that is it often very localized and topical, and may have a regionalized flavor that distinguishes it from other forms of slang. It certainly has an appeal for the young, who aim to be fashionable and trendy in the way they use language just as much as the way they dress. Part of the reason for the short shelf-life of slang is that most words die a natural death, either through excessive use that dulls the lustre of even the most colorful words or descriptions, or through too limited circulation. Overuse is often the fault of the media, who raise to public awareness words that might otherwise have remained the property of the subculture that coined them. Underuse is attributable to the need to restrict slang to subcultures, causing them to drop out of use when group members leave, grow up, etc. Such words are then forgotten, except in the minds of a few, who, when they use them, reveal their age; nothing dates one more than old slang, with *groovy* from the 1960s and *oh you kid*, a very stylish thing to say in 1910. Nevertheless there are certain slang words that persistently bubble below the level of public awareness for centuries, as is the case with criminal cant and all our swearwords. Thus, despite the view that slang is ever-changing, many words are aged in the extreme: Bailey (1985: 40) mentions the following as examples (cited in Gorse, 1796): *blab, chum, cut* (drunk) *ding* (knock down) *mellow* (drunkish) punk. *Lift* (for shoplift) dates from 1526, *pig* (policeman) from 1700, *jug* (prison) from 1800, *bones* (for dice) comes from Chaucer, *booze* and *duds* (clothes) from Dekker and *beat it* (run away) from Shakespeare. Such slang, although it never dies, also has not made it as standard.

In a few cases, slang words join the ranks of standard language: the words *slang, spunk, jazz*, *bus, piano*, and *funky* are a few that have ultimately found their way into respectability. In this way the slang of yesterday becomes the literary language of the next generation. More recently, Hall (2002) reports that even educated, well-read people tell her that slang words are "not slang at all. They are the way we speak now." Often new slang, which appears fresh and original, may in fact involve the recycling of old terms which are new to a new generation of users, generally through exposure to old movies. Another explanation for the aura of creativity surrounding slang is its rarity in formal contexts. A counterview, expressed by several critics of slang, is that force of habit and peer pressure to conform actually restricts the linguistic choices available to the average teenager. For them, slang becomes a drab and boring uniform and only a few skilled speakers have a genuinely wide repertoire in this register.

Excluding Nonmembers and Labeling the "Other"

Slang is frequently derived from a context (such as a prison) in which there is a need to have a private language, often with the intention of being ambiguous and misunderstood in order to exclude outsiders from that particular group. Here, slang is not generated for lack of a lexicon, but from the need to create an identity specific to a particular social group. Often this slang can signal rebelliousness and disrespect for authority, and it flourishes in groups that conflict in some way with the dominant culture (such as prison inmates), by emphasizing the values, attitudes, and interests of the subculture, and thereby marking

social and linguistic identity. In schools, therefore, there are many slang words for those in authority over adolescents, such as prefects and teachers. Ironically, for this reason there are also many slang terms for adolescents who do not fit in with the subculture, such as *geek* or *nerd, lurker, rash* and *bog-fly.*

A less appealing aspect of slang is its pejorative and abusive side. It is frequently used to break norms, to shock and to show disrespect for authority. Typically flippant, irreverent, and lightheartedly indecorous, there are no holds barred, particularly in areas of social taboo. Mocking and unsentimental, slang can be devastatingly cruel and harshly critical of deformity or inadequacy of any kind. Its words aptly summarize group attitudes to outsiders and towards the unfortunate fat, ugly, or mentally disadvantaged people of this world, and are used to label the outsider as 'other.' This accounts for much of the negativity which surrounds its use more generally. In his questionnaire-based research, surveying 377 high-school adolescents, Thurlow (2001) received 100% percent responses to one question: "what words do people at school use for slagging someone off?" (Thurlow, 2001: 27) (*slagging* means to criticize harshly or speak disparagingly). Naturally, such derogatory and pejorative names that are ascribed to certain groups can be extremely hurtful to the recipients, marking them as deviating from some sort of externally imposed norm, and criticizing and excluding those who are socially ostracized for one reason or another. Such language usage is undoubtedly a contributing factor in "the reproduction of social inequalities and power relations" (Thurlow, 2001: 35), and can be harsh, abusive, critical, exclusionary, and coercive. Abusive naming practices reveal the social attitudes of the community of users, distinguishing the outgroup from insiders, and implicitly or explicitly declaring who one is and who one is not. It is this combination of exclusion and bonding that makes slang and swearwords especially attractive to teenagers.

The Sources of Slang

From a linguistic perspective, slang and expletives are typically the lexically full or content words of language: the nouns, verbs, and adjectives and adverbs; the grammatical skeleton (e.g., determiners) are seldom tampered with. But what is more interesting is the syntactic versatility (or vagueness) of slang and expletives, the words frequently acting on demand as adjectives, verbs or nouns: for example, the South African slang word *arb* (possibly derived from *arbitrary*, although the original meaning has shifted) has several different meanings (unexciting, ordinary, not worthy of much comment, boring) and can act as a noun (*I saw this arb walking towards me*) or an adjective (*this arb person suddenly came up*), a verb (*we were just arbing around*), or an expletive (*arb man!*).

While it is conceivable that slang terms could be coined to refer to trees, doors or teaspoons, it is interesting to note that such unexciting areas of life do **not** contain many slang terms. These semantic areas are typically immune from the influence of slang because they refer to commonplace, unexciting areas of life that have no emotive connotations whatsoever. Slang augments the lexicon in those areas in which existing words aren't enough to accommodate the needs of speakers (Bailey, 1985: 12), particularly areas of life that hold a fascination for the subculture that creates and uses these words. If this happens to be a group of motor-bike enthusiasts, one expects many words for motor-bikes, and in teenage groups, these words revolve around typical teenage interests, especially taboo areas.

Thus, one finds an abundance of slang terms in semantic areas relating to (often illicit) enjoyment, fun and pleasure: eating and drinking (often to excess), sleeping, money, cigarettes and drugs, and sexual activity (in the broadest senses). All of these are interesting, enjoyable, exciting and often forbidden to the young. There are also usually slang terms for words that are high-frequency words, such as *nice* and *unpleasant*. Another semantic area in which slang flourishes is the area of social taboo, relating to the embarrassing or sensitive aspects of life: genitalia, scatalogical terms, mental and physical deficiencies, racist terms, conflict, and death.

People who coin slang words draw from a variety of linguistic resources, all reflective of the lighthearted and creative underpinnings of these words. Common sources include alliterations (e.g., *boing-boing* = fat person; *numbnuts* = unlikeable male), metaphor (*swamp donkey / cow / gravel* = unattractive female), acronyms (e.g., *NBS* = nearest bottle store), and antonymy (*beaut* = unattractive woman; *bitching / blind* = nice). Borrowing and adapting from other languages is also a rich source of ideas, and in the Eastern Cape Province of South Africa slang words in Xhosa abound (e.g., *fotloza* = ugly girl), often reflecting a blend of the phonetic properties of each language. For example, the word *costile* (a costly mistake or failure) (pronounced /khosti:lɛ/), is actually derived from the English word *cost* and has the past tense verbal suffix from Xhosa *(-ile)* added, to indigenize the word so that it fits in with the sound and rhythmic structure of the "other" language, thus disguising itself as a non-English word. In the same way *wacooka* is based on the English word *cook*,

with a Xhosa prefix. Similarly, *nqooze,* pronounced to rhyme with *booze*, is a Xhosa-ization of this English slang word itself, and *mnca* (nice) and *nqube* (a party) are pronounced with an alveolar and palatal click, respectively. Borrowings from Afrikaans are just as frequent (*gaar* = drunk; *jol* = party; *klap 'n dos* = have a snooze; *blom* = enjoy oneself).

Euphemism is also evident in the lexicon of slang, reflecting a light-hearted flippancy about serious, disgusting or embarrassing topics such as death (*snuff it, kick the bucket*), pimples (*cheese burgers; warheads*), vomiting (*spray paint; throw chungies*) or being drunk (*running a temperature*). Hyperbole is also frequently evident in such words or phrases, many of which act as idiomatic expressions, not analyzable into component parts (e.g., *drop Garth from the team* = vomit; *pick up stompies* = butt into a conversation). Another common linguistic device is the use of metonymy, with a part referring to the whole (e.g., *fluff / meat* = attractive female). Often pure invention comes to the fore, and neologisms, including phonetic distortions (with accompanying spelling problems) are found in great numbers (e.g., *knarley / fantabulous* = nice, *babinski / schweet*, = attractive girl). Onomatopoeia is also frequently evident (e.g., *ralph* = vomit), as is the experimentation across languages evident in the playful use of the Xhosa click in English words: *overated* has become *nqovarated*, and *overboard* has become *nqovaboard*, each with an African accent and a resounding click at the start. The same sheer enjoyment of sounds is evident in phrases that combine synonymy with rhyme (e.g., *cruising for a bruising* = looking for trouble; *going like a Boeing* = moving fast). Reduplication of sounds is common as well (*goodie-goodie* = prefect; *mshi mshi* = clothes), as is the abbreviation or shortening . . . evident in some words (*woosie* = effeminate person; *civvies* = clothes).

Another ploy is to take a standard English word and shift its denotation (e.g., *channel* = vomit; *tanked / toasted* = drunk). This naturally adds to the delicious confusion wrought by the use of slang, in which the secret code is only shared by those in the know, as it were.

Attitudes toward Slang

Slang has, until recently, been neglected by serious linguists, and either romanticized by its supporters as witty, creative, and vivid, unrestricted by the chains of a standard, or viciously criticized and condemned by prescriptivists as dangerously vulgar nonstandard speech. Although many people approve of slang, and lightheartedly refer to it as "language on a picnic," "the poetry of everyday life" (Hayakawa, 1941: 195), and "a language that rolls up its sleeves, spits on its hands, and goes to work" (Sandburg in Anderson and Trudgill, 1990: 69), others view it less positively. Because it is not accepted as good, formal usage by the majority, those with higher status or responsibility, the 'gate-keepers' of language such as teachers and parents, resist it and disapprove of its use in formal or serious speech or writing, warning that it is a sign of mental laziness that prevents its users from acquiring a wide-ranging vocabulary in standard English. Another reason for its negative associations is that it often serves to mock, ridicule, or hurt others.

Slang also attracts disapproval because it is very closely associated with swearing and profanity (in which the name of a deity is used to express negative affect or disrespect), and distinguishing the two is not always a simple task. While swearing is regarded as "language in its most highly charged state" (Hughes, 1991: 4), generally connected with taboos of some kind, slang terms are not as powerful or as strongly forbidden. For most Western middle and upper classes, swearwords and slang form a continuum of nonstandard forms, with expletives comprising the more shocking or taboo range of words and slang coming closer to acceptability. Research over the years suggests that increasing numbers of former taboo words are regarded now as mild slang terms: Dumas and Lighter (1978: 9) found that most speakers could not clearly distinguish slang from expletives with any degree of reliability, and according to Tweedie (2003) only 16 of the 70 taboo words listed in the earlier edition of *Collins dictionary* remain taboo, and the rest (e.g., *bollocks*) have been downgraded to mere slang or informal expressions on the basis of frequency of use and of the majority view of perceptions of the shock value of these words. Increasingly, erstwhile shocking words such as *fuck* are used so liberally in the media and in some subcultures that their users scarcely notice them.

Who Uses It and Why?

There are two long-standing strong cultural stereotypes regarding slang users. The first is that slang is the primary domain of adolescents, all of whom inevitably use it. The second is that slang (especially words that are more taboo) is largely the domain of males, while females avoid it as unladylike, because of its strong connotations of masculinity and toughness (Jespersen, 1922; Flexner and Wentworth, 1975; Holmes, 1984).

The first of these claims must be made with care: linguistic behavior in adolescence is not simply a matter of conformity to clear and unambiguous role models. While it is tempting to overgeneralize that all

adolescents behave in the same way, there are many thousands of adolescents who do not use slang, and who assert their individualism in ways that uniquely reflect their intelligence and personalities.

The view that males typically use slang is often supported by claiming that male adolescent peer groups are commonly very much larger, more hierarchical, close-knit and competitive than female groups (Romaine, 1984), which are smaller, more intimate, and do not value verbal posturing as much. Also associated with male slang usage is its symbolic rebellion against adult norms, linked to growing social power. However, this stereotypical association between slang usage and males is increasingly subject to critical scrutiny, and linguists have begun to realize that the view may not be at all accurate. As early as 1943, Schlauch regretfully notes tendencies for females to encroach on this all-male precinct, and Hertzler (1965) makes the same point. It would appear that with shifts in power, norms and habits of slang (and expletive) usage are being challenged, and signs of change are revealed in more recent studies by Bailey *et al.* (1976), Staley (1978), Risch (1987), de Klerk (1997) and Sutton (1995), all of whom indicate a growing resistance by females to conformity to expectations regarding the use of both slang and swearwords. Evidence shows that they do use them and in so doing, reveal a need to do so.

The steady lessening of gender differences over the past half-century, particularly in the workplace, has been caused to some extent by feminist rhetoric, and the lack of conformity to the stereotype both within and across gender groups suggests that these words, instead of being regarded exclusively as signs of masculinity *per se*, are increasingly being regarded more as symbols of power more generally, equally available to both gender groups. Linguistic behavior is no longer a simple matter of conformity to clear and unambiguous role models, and linguistic differentiation is neither smooth nor consensual. If female trends in slang (and expletive) usage are shifting, either it could be seen as an attempt by them to mimic male behavior, and associate with the socially dominant group, or there may be an increasing number of women who aim to assert a new image of women that runs contrary to stereotyped images of being pure, sensitive, and caring (Sutton, 1995: 290). Also, ironically, while male adolescents may indeed know and use more slang than females, it might not be because they want to, but simply because they have very little choice: society expects them to.

Individuals must go through the process of working out for themselves whether slang suits their image. For young females, using slang breaks rules and thereby makes a clear statement; for young males not using it makes a different kind of statement. Linguistic choices are only meaningful within and determined by current social circumstances. Critical linguists (e.g., Fairclough, 1992: 26) link linguistic choices to wider social processes, relationships, and power: on the one hand, discourse is seen as reproducing and perpetuating existing social relations and structures, because people enter social interaction with social identities that are preformed and affect their linguistic practice. On the other hand, the potential for change comes when groups with different discourse norms or conventions find themselves interacting, and this is the case when males and females, or adolescents and adults come together and follow slightly different linguistic norms. Their discourse can be seen as representing a kind of delicate social power struggle that may often result in change, both in the mode of discourse and of wider social and cultural domains (Fairclough, 1992: 28–29).

The concept of a linguistic market, derived from Boltanski and Bourdieu (1975) is also useful to describe patterns in slang usage. In terms of this framework, different varieties and styles carry different value in the various linguistic markets operating at any one time in any community. These include the standard, global market, in which legitimate standard language holds the highest value and power, and submarkets, in which nonstandard slang holds more sway. Trudgill's notion of covert prestige (1972) goes some way in recognizing that local market values can conflict with global ones. While users of slang and other vernacular forms know that their varieties are stigmatized in the global hierarchy, it nevertheless pays useful dividends in the local marketplace, and is full of positive meaning in concrete local practice, a prime symbolic asset carrying markedly higher value during the adolescent years than in later years.

For this reason, later in life, when social class and education outweigh age, location (and masculinity) in indicating status, linguistic values shift again, and the types and styles of language that used to wield power are slowly and naturally replaced by other, more widely recognized standard forms (Holmes, 1992: 185), with use of standard forms peaking at age 30–55. Exceptions to this trend are those with less social power, restricted economically or socially, who are far more likely to keep using their local slang as covert status symbols, in order to fit into their local subcommunities. Ironically, those who are successful and who acquire social status along with the trappings of wealth are very likely ultimately to impose and uphold the very taboos against the use of slang that they flouted in their own youth.

Slang, Argot and Ingroup Codes

C Eble, University of North Carolina, Chapel Hill, NC, USA

Slang, argot, and ingroup codes are sets of words and expressions that are motivated by the social and interpersonal functions of language. Their purpose is to bring about a social bond among their users through awareness of shared knowledge. Such vocabulary is usually an alternative to words and expressions in the standard variety of the language. For example, many topics that American college students talk about are time-honored on college campuses and can be referred to with general vocabulary. For social reasons, though, at the beginning of the 21st century American students used *bia* for 'a thoroughly unpleasant female,' *pimp* for 'a popular male,' and *money* for 'very good,' as in "Last night's concert was money."

By comparison with the general vocabulary, such socially salient words and expressions are often short-lived and fall into disuse quickly by being displaced by

Slavic Languages

L A Janda, University of North Carolina, Chapel Hill, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

The Slavic language group contains three subfamilies: (1) East Slavic, consisting of Russian, Belarusian (Belarusan), and Ukrainian; (2) West Slavic, consisting of Polish, Czech, Slovak, and Sorbian (the latter spoken in Germany and also known as Lusatian); and (3) South Slavic, consisting of Bulgarian, Macedonian, Slovene (Slovenian), and Bosnian/Croatian/Serbian (BCS; formerly known as Serbo-Croatian). The Slavs are believed to have expanded from an area corresponding to southwestern Belarus/northwestern Ukraine beginning in the 6th century C.E., an event that contributed to the linguistic differentiation of Late Common Slavic (LCS) into the modern Slavic languages. In the late 9th century a Byzantine mission to the present-day eastern Czech Republic yielded translations of liturgical texts into Old Church Slav(on)ic, a written language presumed to be very close to LCS. These documents have made it possible for us to reconstruct the history of the Slavic languages quite reliably. Orthography follows religion in dividing the Slavic languages into an Eastern/Orthodox Christian group that uses the Cyrillic alphabet (Russian, Belarusian, Ukrainian, Bulgarian, Macedonian, and part of BCS), and a Western/Catholic and Protestant group that uses the Latin alphabet with the addition of diacritics (Polish, Czech, Slovak, Sorbian, Slovene, and part of BCS).

Phonological History

Within the Indo-European language family, the closest relatives to the Slavic languages are the Baltic languages (Latvian and Lithuanian). Both Slavic and Baltic are 'satem' languages, a name based on the Avestan word for 'hundred,' which identifies the reflex of Proto-Indo-European (PIE) *k'* → *s* (and *g'* → *z*), as in the Late Common Slavic (LCS) *sъto* 'hundred'. Peculiar to Slavic (though with some analogues in Baltic and Indo-Iranian languages) is the 'ruki' rule sound change, which caused *s* (*š*) → *x* in positions following *r*, *u*, *k*/*g*, and *i*, as in Proto-Indo-European (PIE) *ousos* → LCS *uxo* 'ear'. 'Ruki' and 'satem' are ancient changes in the development of PIE into Early Proto-Slavic (EPSl). The subsequent era linking EPSl and LCS is marked by sound changes that affected all of Slavic, though their ultimate outcomes are not entirely uniform. Many EPSl-to-LCS sound changes reflect a phonotactic strategy aimed at creating 'ideal' syllables of rising sonority and level tonality, i.e., syllables with CV structure where both the C and V elements had the same (high or low) tonality (also known as 'syllabic synharmony'). The conflict between the most normal structure for a root morpheme, which was CVC, and the ideal syllable structure of CV resulted in the great number of morphophonemic alternations so characteristic of Slavic. The last element in a CVC sequence was in a precarious position: either it was assigned to the syllable containing the preceding CV, in which case sonority constraints made it subject to absorption or loss, or it

was assigned to the following syllable, where tonality constraints could subject it to mutation. We will look at each group of sound changes separately.

Rising Sonority

Rising sonority motivated syllable shape changes CVC → CV and V → CV, which resulted in both loss of final consonants, as in EPSl *su:nus* (cf. Gothic *sunus*) → *synъ* 'son', and prothesis, as in EPSl *esti* (cf. Latin *est*) → *jestь* 'is'. If a syllable peak contained a diphthong (a vowel followed by a sonorant: a glide, nasal, or liquid), its sonority rose but then dipped, and this lack of conformity to rising sonority also motivated changes in syllable structure, mainly monophthongization or metathesis.

Diphthongs ending in a glide monophthongized to yield new vowels:

- *ei* → *i*, as in *zeim-* → *zima* 'winter'
- *åi* → *ě* (known as 'jat'), as in *måix-* → *měxъ* 'fur'
- *eu* → *(j)u*, as in *teu-* → *tjudjь* 'alien'
- *åu* → *u*, as in *låu-* → *luna* 'moon'.

The subsequent development of 'jat' is quite diverse in Slavic.

Diphthongs ending in a nasal monophthongized to yield nasal vowels:

- *e/i* + *m/n* → *ę*, as in *swent-* → *svętъ* 'holy'
- *å/u* + *m/n* → *ǫ*, as in *åmb-* → *zǫbъ* 'tooth'

Polish is the only Slavic language that retains nasality for these vowels (though they have been reorganized: those that developed length became the back nasal *ą*, whereas those that remained short became the front nasal *ę*). The remaining Slavic languages denasalized these vowels, with various results. Thus *svętъ* 'holy' and *zǫbъ* 'tooth' yield, respectively: Russian *sviatoĭ* and *zub*, Polish *święty* and *ząb*, Czech *svatý* and *zub*, Slovene *svet* and *zob*, BCS *svet* and *zub*, Bulgarian *svet* and *z″b*.

Diphthongs ending in a liquid differed in the presence or absence of an initial consonant and in whether the vowel was a 'full' vowel or a reduced vowel ('jer'), and are referred to as ORT (for orC- and olC-), TORT (for CorC, CerC, ColC, and CelC), and TъRT (for CъrC, CъlC, CьrC, CьlC). Overall, these are referred to as the 'TORT' phenomena, and the results (particularly in terms of vowel quality) are quite varied across Slavic. The examples represent only a fraction of the relevant data:

- ORT reflexes show metathesis: *orstъ* 'growth' → Russian *rost*, Polish *-rost*, Czech *růst*, BCS *rast*, Bulgarian *rast*.
- TORT reflexes show an epenthetic vowel in Russian (pleophony, creating two syllables from one), and metathesis elsewhere: *gordъ* 'enclosure' → Russian *gorod*, Polish *gród*, Czech *hrad*, BCS *grad*, Bulgarian *grad*.
- TъRT reflexes are the most varied and hard to characterize by rule: *vъlkъ* 'wolf' → Russian *volk*, Polish *wilk*, Czech *vlk*, BCS *vuk*, Bulgarian *v″lk*.

Syllabic synharmony

Syllabic synharmony was violated when a low tonality consonant was followed by a high tonality vowel (or sonant), or when a high tonality consonant was followed by a low tonality consonant. The solution in both cases was to raise the tonality of the low tonality segment. Raising the tonality of consonants yielded the postalveolar fricatives and affricates conspicuous in the Slavic languages, resulting from the palatalizations of velars. In the first palatalization, *k* → *č*, *g* → *ž*, *x* → *š* before a front vowel or *j* uniformly throughout Slavic: *plåkjåm* → *plačǫ* 'I weep', *gen-* → *žena* 'woman', *du:xe:tei* → *dyšati* 'breathe'. The second (and third) palatalization of velars took place in two environments: after a high front vowel (or diphthong containing one) or before *åi*. This palatalization yielded *k* → *c*, *g* → *z* (*dz* in Polish), *x* → *s* (*š* in West Slavic): *åtikås* → *otьcь* 'father', *kåinå:* → *cěna* 'price', *kuningås* → *kъnęzь* 'prince' (cf. Polish *ksiądz* 'priest'), *någåi* → *nozě* 'leg.DAT/LOC.SG' (cf. Polish *nodze*), *vixås* → *vьsь* 'all' (cf. Czech *všechen*), *xåir-* → *sěr-* 'gray' (cf. Czech *šerý*). The velar palatalizations show a loss (except for Polish) of the stop quality of *g*, and this was part of a larger phenomenon which included the lenition of *g* in all positions to a velar or uvular fricative in East Slavic (except Russian), Czech, Slovak, and Upper Sorbian.

Dentals followed by *j* (and similar clusters) were subject to similar sound changes. Throughout Slavic *sj* → *š* and *zj* → *ž*: *peisjå:m* → *pišǫ* 'I write', *må:zjå:m* → *mažǫ* 'I smear'. Original *dj* (also *deu* and *gti*) and *tj* (also *teu* and *kti*), as in LCS *medja* 'boundary', *světja* 'candle', yielded a variety of reflexes: Russian *mezha/svecha*, Polish *miedza/świeca*, Czech *meze/svíce*, Slovene *meja/sveča*, BCS *međa/svijeća*, Bulgarian *mezhda/sveshch*. The various palatalizations occur both in roots and at morpheme boundaries, where they occasion various morphophonemic alternations of consonants in Slavic languages. The principle of raising the tonality of a consonant followed by a high tonality vowel has been further continued in some languages: Russian has developed phonemic palatalization, such that all nonpalatal consonants are opposed hard to soft, except the dental affricate *ts*; in Polish this goes one step further and dentals are palatalized to palatals (*t/d/s/z/n* → *ć/dź/ś/ź/ń*) before front vowels.

A low tonality vowel following a high tonality consonant (usually *j*) was also subject to the adjustment of syllabic synharmony, and this resulted in the fronting of back vowels: *mårjås* → *morje* 'sea', *sju: tei* → *šiti* 'sew'.

Vowel Distinctions

EPSl had four vowels, all of which could be long or short: *i*, *u*, *e*, *å*. These vowels were reinterpreted as eight LCS vowels, differentiating the long and short vowels qualitatively. Thus long *i:* → *i*, *u:* → *y*, *e:* → *ě*, *å:* → *a*; and short *i* → *ь*, *u* → *ъ*, *e* → *e*, *å* → *o*.

The LCS era (and the law of rising sonority) comes to an end with the loss of the two short high vowels, *ь* ('front jer') and *ъ* ('back jer') in weak positions, commonly known as 'the fall of the jers'. A jer was strong in a syllable preceding a syllable with a weak jer; all other jers were weak. Weak jers were lost, but strong jers attained the status of full vowels. The fall of the jers created new closed (CVC) syllables, new consonant clusters, and many vowel/zero morphophonemic alternations. In this example, the strong jer is underlined: LCS *sъ̲nь/sъna* 'dream.NOM/GEN.SG' yields Russian *son/sna*, Czech *sen/sna*, BCS *san/sna*.

Prosody

LCS had a system of phonemic pitch and subphonemic stress. Although length had been lost in the re-interpretation of vowels, it was subsequently re-established in parts of the Slavic territory. Russian, Belarusian, Ukrainian, and Bulgarian have phonemic stress. BCS and Slovene have phonemic pitch and length. Polish and Macedonian have fixed stress on the penultimate and antepenultimate syllables, respectively. Czech and Slovak have phonemic length and fixed stress on the initial syllable.

Morphological history

Declension

LCS was, and Slavic languages for the most part remain, highly synthetic, with distinct inflectional desinences as well as derivational suffixes and prefixes affixed to roots. EPSl declensions were based mostly on stems with theme vowels, with a few consonantal stems. By the LCS period, the declensions had moved toward association with genders, and the theme vowels were absorbed by sound changes into synthetic desinences that mark case, number, and gender. LCS had three numbers, singular, dual (with restricted case distinctions), and plural, but all the modern languages except Slovene and Sorbian have lost the dual. Slavic maintained much of the PIE case structure, though it merged the ablative with the genitive (restrictive), to yield nominative, genitive, dative, accusative, vocative, locative, and instrumental. The case distinctions (all but the vocative) were subsequently lost in Macedonian and Bulgarian, and the vocative was lost in Russian, Slovene, Slovak, Lower Sorbian, and Belarusian. In addition to the three genders (masculine, feminine, neuter), an animacy distinction developed within masculine during LCS, marked by the substitution of the genitive singular inflection for the accusative singular. Animacy is realized in the plural only by a few languages, in particular Russian and Polish (where it marks only male humans), plus Czech (where it is available only in the nominative plural and dative/locative singular). In LCS, Slavic adjectives were enlarged by the affixation of the corresponding pronominal forms, to create compound adjectives, which initially signaled definite, as opposed to the shorter 'indefinite' adjectives. BSC and Slovene continue this distribution of long vs. short adjectives. Polish, Czech, and Russian expanded the long compound adjectives, and have restricted the short adjectives to predicate position. Bulgarian and Macedonian maintained only the short adjectives, and developed a postposed article to mark definiteness. The LCS personal pronouns had both long (emphatic) and short (enclitic) forms, and the West Slavic and South Slavic languages continue this distinction.

Conjugation

The most important development for verbs is the evolution of Slavic aspect, which is peculiar because it obligatorily distinguishes perfective from imperfective in all verbal forms, and because the imperfective is more complex and unmarked (whereas it is the marked category in most other languages with this distinction). Aspect is expressed in simplex stems, and via an elaborate system of derivational prefixes and suffixes. The PIE supine, middle, subjunctive, and perfect disappeared in Slavic (but Bulgarian and Macedonian have a new perfect), and the LCS aorist and imperfect tenses have been lost in both East Slavic and West Slavic (except Sorbian). The only two tenses that the modern languages all share are a past (derived from a resultative participle) and a nonpast (usually interpreted as a future if perfective, but as a present if imperfective). Bulgarian and Macedonian lack an infinitive. The Slavic imperative has been innovated from the PIE optative, and the conditional is expressed paraphrastically using an auxiliary from *byti* 'be'. LCS had no distinct future tense, but used instead the perfective nonpast or an auxiliary verb with a participle or infinitive. LCS had a system of four participles expressing present vs. past and active vs. passive; these survive in their entirety only in

Russian. Like its nouns, EPSl verbs were inflected by combining a stem with a theme vowel and a desinence (with the exception of five 'athematic' verbs), and again sound changes obliterated the distinct role of the theme vowel by LCS. In the modern languages, verbs express aspect, tense, person, number, and, in certain forms, gender.

Slobin, Dan Isaac (b. 1939)

M Brdar, University of Osijek, Osijek, Croatia

© 2006 Elsevier Ltd. All rights reserved.

Dan I. Slobin, an outstanding American psycholinguist whose research has had enormous influence on the field of language acquisition studies, was born in Detroit, Michigan, on May 7, 1939. He graduated in psychology from the University of Michigan, Ann Arbor in 1960. He received his M.A. and Ph.D. degrees from Harvard in 1962 and 1964, respectively. In 1964 he joined the Department of Psychology at the University of California at Berkeley, where he was appointed to the position of Full Professor in 1972.

Slobin's research has focused on the specific phenomena of language acquisition as a window on the more general issue of the intricate relation of language to cognition and culture. Specifically, he is concerned with cognitive structures and mechanisms giving rise to the emergence of a linguistic system in mind, but also the effects of language on thinking. One of his influential proposals concerning the identification of universal developmental patterns was that the acquisition device contains a set of procedures and inference rules for analyzing linguistic data, subsequently called operating principles, rather than an actual body of linguistic knowledge in the form of grammatical rules. Slobin (1985) proposes close to 40 such principles, which he describes as "procedures for perceiving, storing and analyzing linguistic experience" (Slobin, 1985: 1158).

The deployment of a cross-linguistic research design, making use of both experimental and naturalistic methods in an attempt to identify universal developmental patterns, on the one hand, and his functionalist interest in uncovering cognitive and communicative bases of linguistic structures, on the other, naturally led Slobin to extend his research agenda in recent years, assuming a typological perspective, looking for the effects of particular types of languages on psycholinguistic processes – what he has come to call "thinking for speaking" – and even going beyond it (e.g., in studying sign languages in order to examine the extent to which universals of language and language behavior are determined by modality (vocal/auditory vs. manual/visual)). Thus, in a series of recent papers, Slobin applies Talmy's (1985) distinction between satellite- and verb-framed languages as representing different types of lexicalization pattern in the analysis of the conceptualization and verbalization of motion events in languages such as English and Russian (satellite framed) versus French, Spanish, Turkish, and Hebrew (verb framed). The preferred construction type in these languages

Russian. Like its nouns, EPSl verbs were inflected by combining a stem with a theme vowel and a desinence (with the exception of five 'athematic' verbs), and again sound changes obliterated the distinct role of the theme vowel by LCS. In the modern languages, verbs express aspect, tense, person, number, and, in certain forms, gender.

Slobin, Dan Isaac (b. 1939)

M Brdar, University of Osijek, Osijek, Croatia

© 2006 Elsevier Ltd. All rights reserved.

Dan I. Slobin, an outstanding American psycholinguist whose research has had enormous influence on the field of language acquisition studies, was born in Detroit, Michigan, on May 7, 1939. He graduated in psychology from the University of Michigan, Ann Arbor in 1960. He received his M.A. and Ph.D. degrees from Harvard in 1962 and 1964, respectively. In 1964 he joined the Department of Psychology at the University of California at Berkeley, where he was appointed to the position of Full Professor in 1972.

Slobin's research has focused on the specific phenomena of language acquisition as a window on the more general issue of the intricate relation of language to cognition and culture. Specifically, he is concerned with cognitive structures and mechanisms giving rise to the emergence of a linguistic system in mind, but also the effects of language on thinking. One of his influential proposals concerning the identification of universal developmental patterns was that the acquisition device contains a set of procedures and inference rules for analyzing linguistic data, subsequently called operating principles, rather than an actual body of linguistic knowledge in the form of grammatical rules. Slobin (1985) proposes close to 40 such principles, which he describes as "procedures for perceiving, storing and analyzing linguistic experience" (Slobin, 1985: 1158).

The deployment of a cross-linguistic research design, making use of both experimental and naturalistic methods in an attempt to identify universal developmental patterns, on the one hand, and his functionalist interest in uncovering cognitive and communicative bases of linguistic structures, on the other, naturally led Slobin to extend his research agenda in recent years, assuming a typological perspective, looking for the effects of particular types of languages on psycholinguistic processes – what he has come to call "thinking for speaking" – and even going beyond it (e.g., in studying sign languages in order to examine the extent to which universals of language and language behavior are determined by modality (vocal/auditory vs. manual/visual)). Thus, in a series of recent papers, Slobin applies Talmy's (1985) distinction between satellite- and verb-framed languages as representing different types of lexicalization pattern in the analysis of the conceptualization and verbalization of motion events in languages such as English and Russian (satellite framed) versus French, Spanish, Turkish, and Hebrew (verb framed). The preferred construction type in these languages

predisposes their speakers to deal differently with the motion events encoded in linguistic utterances.

Slovak

R A Rothstein, University of Massachusetts, Amherst, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Slovak is a West Slavic language, most closely related to Czech. It is the native language of some 4.6 million residents of Slovakia, of somewhere between 300 000 and 500 000 residents of the Czech Republic, and of additional speakers in Hungary, Poland, Romania, Serbia, and North and South America.

Orthography

Like other Slavic languages that were historically in the cultural sphere of the Western Church, Slovak uses the Latin alphabet with diacritic marks. Long vowels are marked by an acute accent, *ô* represents the diphthong [uo], and *ä* traditionally represents the vowel [æ], which almost all speakers replace with [ɛ]. The letters *i* and *y* both represent [i], and *í* and *ý* both represent [iː]; the distinction is etymological. Digraphs are used to spell the voiceless velar fricative (*ch*) and the voiced dental and alveolar affricates (*dz* and *dž*, respectively). The voiceless alveolar affricate and the voiced and voiceless alveolar fricatives are represented, respectively, by *č*, *ž*, and *š*. Palatal stops and sonorants are not specially marked before the vowels *e*, *i*, and *í* or the diphthongs *ia*, *ie*, *iu*; elsewhere they are indicated by diacritics: *ť*, *ď*, *ľ*, *ň*. Certain words and categories of words constitute exceptions to this rule for spelling palatals; thus, there is a contrast between the adverb *stále* 'constantly,' pronounced [stáľe], which follows the rule, and the adjective form *stále* 'constant,' pronounced [stále], which does not.

Phonology

The Slovak phonemic inventory consists of fifteen vocalic segments (six short vowels, five long vowels, and four diphthongs) and 27 consonantal ones. Most speakers have only five distinct short vowels, the basic phonetic realizations of which are [i], [ɛ], [ɐ], [ɔ] and [u] (orthographic *i*, *e/ä*, *a*, *o*, *u*), but the different alternation patterns of orthographic *ä* and *e* (the former alternates with *ia*; the latter with *á* or *ia*) are grounds for treating them as representing distinct phonemes. The five long vowels correspond to the short vowels, but /ó/ occurs only in nonnative words, and the distribution of /é/ outside of nonnative words is limited. The four diphthongs are /uo/, /ie/, /ia/, and /iu/, but the last of these seems always to result from a process of contraction and may therefore not be a phoneme. The diphthongs behave like long vowels with respect to phonologically or morphologically conditioned processes of shortening and lengthening, but the relationships between the long vowels and diphthongs on the one hand and the short vowels on the other is mediated by various contextual constraints. The liquids /r/ and /l/ can be syllabic and in that role distinguish length.

A so-called 'rhythmic law' that operates in Central Slovak dialects and in the standard language mandates the shortening of a syllable that follows a long syllable (one containing a long vowel or a diphthong). Thus, in the masculine nominative singular of adjectives, we find *hladký* 'smooth,' but *krátky* 'short' and *riedky* 'rare.' The rhythmic law does not apply in certain grammatical and derivational contexts, e.g., the declension of adjectives derived from animal names (e.g., *vtáčí* 'bird's).

predisposes their speakers to deal differently with the motion events encoded in linguistic utterances.

Phonology

The Slovak phonemic inventory consists of fifteen vocalic segments (six short vowels, five long vowels, and four diphthongs) and 27 consonantal ones. Most speakers have only five distinct short vowels, the basic phonetic realizations of which are [i], [ɛ], [ɐ], [ɔ] and [u] (orthographic *i*, *e/ä*, *a*, *o*, *u*), but the different alternation patterns of orthographic *ä* and *e* (the former alternates with *ia*; the latter with *á* or *ia*) are grounds for treating them as representing distinct phonemes. The five long vowels correspond to the short vowels, but /ó/ occurs only in nonnative words, and the distribution of /é/ outside of nonnative words is limited. The four diphthongs are /uo/, /ie/, /ia/, and /iu/, but the last of these seems always to result from a process of contraction and may therefore not be a phoneme. The diphthongs behave like long vowels with respect to phonologically or morphologically conditioned processes of shortening and lengthening, but the relationships between the long vowels and diphthongs on the one hand and the short vowels on the other is mediated by various contextual constraints. The liquids /r/ and /l/ can be syllabic and in that role distinguish length.

A so-called 'rhythmic law' that operates in Central Slovak dialects and in the standard language mandates the shortening of a syllable that follows a long syllable (one containing a long vowel or a diphthong). Thus, in the masculine nominative singular of adjectives, we find *hladký* 'smooth,' but *krátky* 'short' and *riedky* 'rare.' The rhythmic law does not apply in certain grammatical and derivational contexts, e.g., the declension of adjectives derived from animal names (e.g., *vtáčí* 'bird's).

The consonants that arose from the historical palatalization of velars or from the deiotation of clusters consisting of dental stop or fricative plus glide have lost their palatal character. The historical palatalization of dental consonants, on the other hand, has given rise to a series of palatal consonants: *ť*, *ď*, *ň*, *ľ*. As in most other Slavic languages, final voiced obstruents lose voicing before pause. In obstruent clusters both within phonological words and between words, there is regressive assimilation with respect to voicing. Before a word-initial vowel or sonorant, a word-final obstruent is voiced; such voicing may also occur at morpheme boundaries within words. The laryngeal fricative represented by *h* devoices to the velar fricative *ch*, but when the latter becomes voiced, there is free variation between a voiced velar fricative [ɣ] and *h*. The voiced labiodental fricative *v* behaves like an obstruent at the beginning of a phonological word, but does not cause voicing of a preceding voiceless obstruent within a word. It is realized as [w] in word-final position and is generally realized as [w] word-internally in the environment V_C.

The primary word stress is on the initial syllable and can thus fall on a monosyllabic preposition, especially if the following noun or pronoun is monosyllabic, e.g., *pOd ňou* 'under it,' but also potentially *dO prácy* 'to work.' Unstressed vowels are not reduced, and words longer than three syllables alternate unstressed and secondarily stressed syllables.

Morphology

Nouns distinguish six cases (nominative, accusative, genitive, dative, instrumental, locative); a few masculine nouns have vestigial vocative forms (e.g., *synku* 'son'). Three genders (masculine, feminine, neuter) are distinguished in the singular by agreement phenomena, and a masculine animate subgender can also be distinguished by its syncretism of accusative and genitive and by the ending *-ovi* for dative and locative singular. Certain classes of semantically inanimate masculine nouns also show the accusative-genitive syncretism (e.g., names of trees, mushrooms, diseases: *sťať duba* 'cut down an oak tree'; *nájsť hríba* 'find a boletus mushroom'; *mať vreda* 'have an ulcer').

In the plural there is a binary distinction of masculine-personal (nouns referring to male human beings) and nonmasculine-personal (all other nouns); they are distinguished by the nominative endings, by agreement phenomena, and by the accusative-genitive syncretism of the former vs. the accusative-nominative syncretism of the latter. Adjectives and third-person pronouns also distinguish three genders in the singular and two in the plural; the past-tense forms of verbs show a three-way distinction in the singular but have only a single form for the plural. Some nouns have only plural forms (e.g., *vidly* 'pitchfork[s]'); others are used primarily in the singular (e.g., mass and abstract nouns) but have potential plural forms that usually acquire specialized meanings (e.g., *pivo* 'beer' vs. *pivá* 'kinds or portions of beer'; *láska* 'love' vs. *lásky* 'objects of affection').

Noun declensions are largely gender-based: the masculine and neuter declensions have most endings in common in the singular, while the three feminine declensions in the singular (one for nouns ending in *-a* in the nominative singular and two for those ending in a consonant, i.e., with zero-ending) also share most endings. There is a class of masculine nouns ending in *-a* that refer to male human beings; they follow the masculine declension except for the genitive and accusative singular, which use the *u*-ending of the feminine *a*-declension. In the plural, feminine and neuter nouns have common oblique-case endings, which are different from those of masculine nouns. The traditional presentation of multiple declensional types is based on the fact that certain case endings are dependent on the nature of the final stem consonant – whether it is 'soft' (palatal or 'historically soft,' i.e., the result of historical palatalization or deiotation) or not. Cf. dative singular *žene* vs. *ulici*, which traditional grammars describe as belonging to different declensional types (*žena* 'wife' vs. *ulica* 'street').

Most inherited consonant mutations have been lost from noun declensions. The remaining mutations affect velars and dentals in the masculine personal nominative plural (e.g., *vojak/vojaci* 'soldier[s]'; *Američan/Američania* 'American[s],' with the alternation /n/ to /ň/; *pilot/piloti* 'pilot[s],' with /t/ to /ť/) and dentals in the locative singular of all three genders (e.g., *sused/susede* 'neighbor,' *žena/žene*, *mesto/meste* 'city'). Noun declensions do show quantitative alternations of vowels, for example, between forms with an ending and forms with a zero ending (e.g., NOM/ACC sg *chlieb* vs. GEN sg. *chleba* 'bread,' NOM sg. *ruka* vs. GEN pl. *rúk* 'hand; arm').

Slovak verbs belong to one of two aspectual categories, perfective or imperfective; there are also some biaspectual verbs (e.g., *absorbovať* 'absorb,' *pomstiť* 'avenge'). Perfective verbs express accomplishments or transitions; imperfective verbs express states or activities/processes. Imperfective verbs are typically unprefixed; adding a prefix perfectivizes the verb, sometimes also adding an additional semantic component (e.g., *písať* 'write = engage in the activity of writing'/*napísať* 'write = get something written' vs. *prepísať* 'rewrite,' *opísať* 'describe,' *popísať* 'write a lot'). There are also productive ways of imperfectivizing a perfective verb through a change in suffix and/or the stem (e.g., *prepisovať* 'engage in the activity of

rewriting,' *opisovat'* 'engage in the activity of describing'). Occasionally, corresponding verbs are based on different stems (e.g., imperfective *brat'* vs. perfective *vziat'* 'take'), and some verbs have no corresponding verb of the opposite aspect (e.g., imperfective *mat'* 'have' or perfective *vydržat'* 'bear, stand').

Imperfective verbs have synthetic forms for past and present tense and analytic forms for the future tense; perfective verbs form their past tense in the same way as imperfective verbs, but the forms that look like the present-tense forms of imperfective verbs normally express future tense (or, under certain circumstances, potentiality). An analytic pluperfect tense is formed mostly from perfective verbs. The perfective/imperfective distinction is also present in infinitives, imperatives, and conditional/subjunctive forms. The last of these is formed analytically and distinguishes present vs. past ('would X' vs. 'would have X'). Imperfective verbs form verbal adjectives and adverbs expressing simultaneity, while perfective verbs form verbal adjectives and adverbs that express temporal precedence or subordination to the action of the main verb. Both perfective and imperfective transitive verbs form passive participles, which can be used with *byt'* 'be' to form passive constructions.

Within the imperfective aspect, a further distinction is made between determinate and indeterminate verbs of motion. The former designate motion in a single direction on a single occasion, while the latter do not have those restrictions and can therefore designate repeated motion, the ability to move, etc. (e.g., determinate *ist'* vs. indeterminate *chodit'*). Many imperfective verbs also have derived iteratives that express repeated, often regular, actions (e.g., *hrávat'* 'play frequently' from *hrat'* 'play').

Most of the inherited consonant alternations have been eliminated from present-tense paradigms, except for the alternation between palatals and dentals (*idiem* 'I'm going,' *idieš* 'you're going' vs. *idú* 'they're going'; cf. *pečiem, pečieš, pečú* 'I'm baking, etc.,' and the corresponding Polish forms *piekę*, *pieczesz, pieką*). Other inherited consonant alternations are reflected in the relation between infinitive and present tense (*písat'* 'to write' vs. *píšem* 'I write'), past tense and present tense (*mohol* 'he could' vs. *môže* 'he can'), or perfective and derived imperfective (*podtvrdit'* 'confirm – pf.' vs. *potvrdzovat'* 'confirm – impf.'). Quantitative alternations of vowels appear in conjugation (e.g., *piect'* 'to bake' vs. *pečiem*) and in the derivation of imperfective from perfective verbs (e.g., *kúpit'* vs. *kupovat'* 'buy' or *skryt'* vs. *skrývat'* 'hide'), as well as in nonverbal derivation (e.g., *Nitran* 'man from Nitra' vs. *Nitrianka* 'woman from Nitra').

Syntax

Slovak word order is relatively free and is used, together with sentence intonation, to express the informational structure of the utterance. Thus, the rheme normally follows the theme in emotionally neutral speech. Pronominal and some verbal clitics follow the first stressed word in a sentence. Among them is the particle *sa*, which is historically the enclitic accusative form of the reflexive and reciprocal pronoun. The reciprocal function is still present (e.g., *poznáme sa* 'we know one another'), but true reflexive uses are rare (e.g., *bránit' sa* 'defend oneself'). Verbs with *sa* can express a variety of meanings, among other things, a kind of middle voice (e.g., *umývat' sa* 'wash/wash up/get washed') and also an intransitive verb with an unaccusative subject (e.g., *lekcia sa začína* 'class is beginning'). They can also be used in passive constructions with unexpressed agent (e.g., *reči sa hovoria a chlieb sa je* 'speeches are spoken, but bread is eaten'). As in some other Slavic languages, *sa* has acquired the function of a generic human subject, parallel to German *man* or French *on*, with third-person singular agreement (e.g., *hovorí sa* 'they/people say').

The enclitic dative form of the reflexive and reciprocal pronoun, *si*, occurs both in its literal meaning (e.g., *pomáhat' si* 'help one another' or 'help oneself') and like *sa*, as a component of *reflexiva tantum* (e.g., *všímat' si* 'notice'; cf. *bát' sa* 'be afraid'). Both *sa* and *si* also combine with prefixes to produce a variety of Aktionsart meanings (e.g., *nasediet' sa* 'have one's fill of sitting,' *pospat' si* 'have oneself a nap').

First- and second-person subject pronouns are normally used only for contrast or emphasis; third-person subject pronouns are typically dropped after their first use, unless a previous theme has been reintroduced. Nonfamiliar address uses second-person plural forms of pronouns and verbs.

Lexicon

In addition to preserving its Common Slavic patrimony, the Slovak lexicon has been open to borrowings and adaptations from neighboring languages. Among the earliest borrowings were elements of Christian terminology from Latin, often via German. Throughout the centuries, those two languages, as well as Czech, Hungarian, and Romanian have been important linguistic donors (Slovak has also contributed to Hungarian); in more recent times, Polish, Russian, French, and English have also served as source languages. In the last decades, the role of internationalisms and Anglicisms has been especially important.

Dialectology

The three major dialect areas are Western Slovak, which is transitional to Moravian Czech; Central Slovak, which served as the basis for the literary language; and Eastern Slovak, which is transitional to Polish. The most striking feature of Eastern Slovak is the lack of quantitative distinctions and a tendency to penultimate stress. Central and Western Slovak both distinguish long and short vowels, but the 'rhythmic law' that (with a variety of systematic exceptions) prevents two successive long syllables applies only in Central Slovak. Central and Western Slovak both have initial stress.

History

The incorporation of the Slovak lands into the Hungarian kingdom that was established at the end of the 10th century separated the Slovaks from the Czechs, who maintained their independence until being subdued by the Habsburgs in 1648. The written language of the Hungarian kingdom, and therefore also of Slovakia, was Latin, but thanks to continuing contacts with their Czech brethren, Slovaks began to use Czech as a written language as well. This was especially true after the establishment of Charles University in Prague in 1348, where Slovaks were among the students, and with the influence of the Hussite movement in the 15th century. From the beginning, the Czech written by Slovaks showed the influence of spoken Slovak.

As early as the 15th century there were efforts to write in Slovak, but the first comprehensive effort to create a Slovak literary standard was by a Catholic priest, Anton Bernolák, at the end of the 18th century, who based his norms on the Western Slovak dialects. Perhaps because Western Slovak is closest to Czech, Bernolák's project did not win general acceptance. Slovak Protestants continued to base their writing on the language of the Czech Kralická Bible.

In the middle of the 19th century, Ľudovít Štúr and his colleagues proposed a new literary standard based on the Central Slovak dialects, and this became the basis of the modern Slovak literary language. During the first Czechoslovak Republic (1918–1938), Slovak linguists had to cope with the official doctrine of a single Czechoslovak language, and after World War II the question of the relationship between the Slovak and Czech languages was still on the agenda. Since the creation of two independent states in 1989, there is evidence of decreasing mutual intelligibility, especially among the younger generation of Slovaks and Czechs, who are less exposed to mass media in the other language.

Early dictionaries from the Slovak region (part of the Kingdom of Hungary) were bilingual or multilingual dictionaries with Latin as the source language. The target languages were Hungarian, Early New High German, and more or less 'Slovakified' Czech (for Slovaks, this fulfilled the role of their own written standard from the 14th century) or dialectical variants of 'cultural' Slovak (from the 16th century). Latin schools often used copies of Klaret's *Glossarius* and Slovak prints of J. Amos Comenius' *Orbis Pictus*. The first dictionary of cultural Slovak was the *Trnavský slovník* (1648), which was a trilingual dictionary (Latin, Hungarian, and Slovak) arranged alphabetically. One of the important dictionaries that tried to achieve linguistic and orthographic standardization of Slovak was the *Kamaldulský slovník* (*Syllabus Dictionarij Latino-Slovenicus*, 1763), which was compiled by monks of the Camaldul order, who were translating the Bible into Slovak.

During the national revival (1780–1849), the six-volume *Slowár Slowenskí Česko–Laťinsko–Nemecko–Uherskí* by A. Bernolák was published in 1825–1827, representing the first codification of

Slovak based on the western Slovak dialect. This dictionary achieved greater standardization by separating the features of standard written Slovak from dialectical and Czech terms. One example of the second codification of Slovak, led by Ľudovít Štúr (1815–1856) and based on the central Slovak dialect, is the two-volume *Noví slovensko-maďarskí a maďarsko-slovenskí slovník* (1848–1849) by Š. Jančovič. Dictionaries in the period 1849–1918, for example the *Slovensko-maďarsko-nemecký slovník* by J. Loos (1870) or the *Česko-slovenský a slovensko-český slovník* (1896) by K. Kálal and K. Salva, reflected the reform of Štúr's orthography and gradual orthographic stabilization.

After 1918 (when Slovakia became part of Czechoslovakia), a number of comparative dictionaries and terminological dictionaries (particularly in the fields of administration and law) were published showing the differences between Czech and Slovak and reflecting the changed sociocultural situation of Slovak in the new political structure. The *Slovenský frazeologický slovník* (1933) by P. Tvrdý was the first monolingual dictionary of Slovak (*frazeologický*, or 'phraseological,' means that entries were illustrated by example set phrases and collocations). In the 1940s, preparations to publish a modern monolingual dictionary drawing on a wealth of examples were carried out simultaneously at two different locations: the *Matica slovenská*, the well-established cultural institute and publishing house, and the newly founded (1942) Slovak Academy of Sciences and Arts. After World War II, the Academy took over the project and eventually published a five-volume dictionary of the Slovak language (1959–1968) under the supervision of Š. Peciar. This dictionary drew on texts from the period 1860 to 1960 and contained 120 000 entries. In the 1950s and 1960s, the Academy also coordinated the creation of a number of terminological dictionaries under the supervision of J. Horecký. Among all the bilingual dictionaries, the Slovak–Russian ones, based on the theories of translation equivalence and 'translational meaning,' stood out in terms of size and quality. In 1987 the *Krátky slovník slovenského jazyka* (Kačala *et al.*), which is now in its fourth edition, was published. Gradually, more and more dictionaries are being published specializing in various aspects of lexis: frequency (*Frekvencia slov v slovenčine* by Mistrík, 1968), inversion (*Retrográdny slovník* by Mistrík, 1976), synonyms (*Synonymický slovník slovenčiny* edited by Pisárčiková, 1995), foreign words (numerous dictionaries by M. Šalingová), and morphemes (*Morfematický slovník slovenčiny* by Sokolová *et al.*, 1999). The Academy's long-term projects are to produce the kind of dictionaries that form the lexicographical basis for every language. At the time of writing, it has published five volumes (of seven planned) of the *Historický slovník slovenského jazyka* (supervised by M. Majtán, 1991–2000) and the first volume (of three planned) of the *Slovník slovenských nárečí* (supervised by I. Ripka, 1994). The *Etymologický slovník* by Ľ. Králik is currently being printed (2005).

An important ongoing project of Slovak lexicography of the 21st century is the six-volume *Slovník súčasného slovenského jazyka*, which is based on data from the Slovak National Corpus and the Internet.

Slovakia: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Until 1992, Slovakia was a federated state within Czechoslovakia. It separated from the Czech Republic when that country split in 1993. The official language of the country is Slovak, a Western Slavic language, with a Roman script. Slovak differs only slightly from Czech and is by and large mututally intelligible with it.

The country has a population of about 5 379 500 (as of June, 2004). According to the 2001 census, the Slovaks make up 85.8% of this population. The largest minority group is Hungarians (9.7%). In addition to Hungarians, there are Romanies (1.7%), speaking mainly Carpathian Romani and some, Vlax Romani, and a small group of Czech speakers (0.8%). There are even smaller numbers of Ukrainian, Rusyn, Russian, German, Polish, and Croatian speakers.

The Minority Language Law, accepted in 1999, ensures that speakers of minority languages in

Slovak based on the western Slovak dialect. This dictionary achieved greater standardization by separating the features of standard written Slovak from dialectical and Czech terms. One example of the second codification of Slovak, led by L'udovít Štúr (1815–1856) and based on the central Slovak dialect, is the two-volume *Noví slovensko-maďarskí a maďarsko-slovenskí slovník* (1848–1849) by Š. Jančovič. Dictionaries in the period 1849–1918, for example the *Slovensko-maďarsko-nemecký slovník* by J. Loos (1870) or the *Česko-slovenský a slovensko-český slovník* (1896) by K. Kálal and K. Salva, reflected the reform of Štúr's orthography and gradual orthographic stabilization.

After 1918 (when Slovakia became part of Czechoslovakia), a number of comparative dictionaries and terminological dictionaries (particularly in the fields of administration and law) were published showing the differences between Czech and Slovak and reflecting the changed sociocultural situation of Slovak in the new political structure. The *Slovenský frazeologický slovník* (1933) by P. Tvrdý was the first monolingual dictionary of Slovak (*frazeologický*, or 'phraseological,' means that entries were illustrated by example set phrases and collocations). In the 1940s, preparations to publish a modern monolingual dictionary drawing on a wealth of examples were carried out simultaneously at two different locations: the *Matica slovenská*, the well-established cultural institute and publishing house, and the newly founded (1942) Slovak Academy of Sciences and Arts. After World War II, the Academy took over the project and eventually published a five-volume dictionary of the Slovak language (1959–1968) under the supervision of Š. Peciar. This dictionary drew on texts from the period 1860 to 1960 and contained 120 000 entries. In the 1950s and 1960s, the Academy also coordinated the creation of a number of terminological dictionaries under the supervision of J. Horecký. Among all the bilingual dictionaries, the Slovak–Russian ones, based on the theories of translation equivalence and 'translational meaning,' stood out in terms of size and quality. In 1987 the *Krátky slovník slovenského jazyka* (Kačala *et al.*), which is now in its fourth edition, was published. Gradually, more and more dictionaries are being published specializing in various aspects of lexis: frequency (*Frekvencia slov v slovenčine* by Mistrík, 1968), inversion (*Retrográdny slovník* by Mistrík, 1976), synonyms (*Synonymický slovník slovenčiny* edited by Pisárčiková, 1995), foreign words (numerous dictionaries by M. Šalingová), and morphemes (*Morfematický slovník slovenčiny* by Sokolová *et al.*, 1999). The Academy's long-term projects are to produce the kind of dictionaries that form the lexicographical basis for every language. At the time of writing, it has published five volumes (of seven planned) of the *Historický slovník slovenského jazyka* (supervised by M. Majtán, 1991–2000) and the first volume (of three planned) of the *Slovník slovenských nárečí* (supervised by I. Ripka, 1994). The *Etymologický slovník* by Ľ. Králik is currently being printed (2005).

Until 1992, Slovakia was a federated state within Czechoslovakia. It separated from the Czech Republic when that country split in 1993. The official language of the country is Slovak, a Western Slavic language, with a Roman script. Slovak differs only slightly from Czech and is by and large mututally intelligible with it.

The country has a population of about 5 379 500 (as of June, 2004). According to the 2001 census, the Slovaks make up 85.8% of this population. The largest minority group is Hungarians (9.7%). In addition to Hungarians, there are Romanies (1.7%), speaking mainly Carpathian Romani and some, Vlax Romani, and a small group of Czech speakers (0.8%). There are even smaller numbers of Ukrainian, Rusyn, Russian, German, Polish, and Croatian speakers.

The Minority Language Law, accepted in 1999, ensures that speakers of minority languages in

communities where the minority represents at least 20% of the population, have the right to be educated in their native language and to use their native tongue in all official contacts and transactions with local and state authorities. Hungarian, the most widely spoken minority language, is represented by a couple of daily and weekly newspapers and some hours of weekly radio and TV broadcasts in the Slovak media. The number of children attending Hungarian schools has increased considerably over the last 10 years, as more parents recognize the importance of native-language education.

The literacy rate is very high in Slovakia. In terms of second languages, 30% of the population speaks Russian, 20% speaks German, and 14% speaks English. Since the breakup of Czechoslovakia, Russian lost its prominant role in foreign language education. The most commonly taught languages in schools are German, English, French, and Spanish.

Introduction

Overview

Slovene (or Slovenian), the titular language of the Republic of Slovenia, is spoken by some 2.4 million people, including speakers in bordering areas in Italy, Austria, and Hungary as well as in diaspora communities in Argentina, Australia, Canada, and the USA.

Together with Bosnian, Croatian, and Serbian (Serbo-Croatian), Slovene makes up the Western subgroup of the South Slavic branch of the Slavic languages (Indo-European). Slovene transitions to the Čakavian and Kajkavian dialects of Croatian. It is less close to the Štokavian dialect, the basis for the Bosnian, Croatian, and Serbian standard languages. Ancient connections to the central dialect of Slovak (West Slavic) are evident.

Slovene is traditionally divided into seven dialects, each of which has further dialect differentiation: (I) littoral dialects, spoken partly in Italy; (II) Carinthian, spoken mostly in Austria; (III) Upper Carniolan; (IV) Lower Carniolan; (V) Styrian; (VI) Pannonian, spoken partly in Hungary; (VII) Rovte (Figure 1). There are 48 distinct local varieties.

Standard Slovene is constructed of features from various dialects and historical stages of Slovene and does not correspond exactly to any one dialect. Even in the capital, Ljubljana, everyday speech differs in fundamental ways from the standard; compare standard: *kaj mislite*? 'what do you think?' and colloquial: *kva misl̥te*?

Historical Development and Emergence of Literary Language

By the 6th or 7th century A.D., Proto-Slovene was spoken in an area bounded by the Tagliamento River, the Gulf of Trieste, Linz and the outskirts of Vienna, and the southern end of Lake Balaton. The Proto-Slovene speech territory gradually diminished in the medieval period as speakers shifted to Friulian, Italian, German (Standard German), and Hungarian, leaving a core area today consisting of the Republic of Slovenia plus border areas in Italy, Austria, and Hungary.

The earliest surviving documents are the Freising Folia, liturgical texts composed around 1000 A.D., which are among the oldest attestations of any Slavic language. There are a few surviving Slovene documents dating from then until the middle of the 16th century, mostly religious and legal texts. The first printed books in Slovene are Primus Truber's (1508–1586) *Catechismus* (1550) and Jurij Dalmatin's (1547–1598) translation of the Bible (1584), which mark the first attempt at a standard language. Truber modeled the language on the speech of Ljubljana and his native Lower Carniolan. The Counter–Reformation submerged Truber's legacy, while the Protestants developed a regional literary language in the northeast.

Until the 19th century, Slovene remained secondary to the state language, German (Standard German), and, regionally, Italian and Hungarian. Modern standard Slovene dates to Jernej Kopitar's 1809 grammar, the prestige of which was elevated by the poet France Prešeren (1800–1849) and the intellectual circle around Sigismund Zois (1747–1819). The orthographic system essentially as it is found today

Introduction

Overview

Slovene (or Slovenian), the titular language of the Republic of Slovenia, is spoken by some 2.4 million people, including speakers in bordering areas in Italy, Austria, and Hungary as well as in diaspora communities in Argentina, Australia, Canada, and the USA.

Together with Bosnian, Croatian, and Serbian (Serbo-Croatian), Slovene makes up the Western subgroup of the South Slavic branch of the Slavic languages (Indo-European). Slovene transitions to the Čakavian and Kajkavian dialects of Croatian. It is less close to the Štokavian dialect, the basis for the Bosnian, Croatian, and Serbian standard languages. Ancient connections to the central dialect of Slovak (West Slavic) are evident.

Slovene is traditionally divided into seven dialects, each of which has further dialect differentiation: (I) littoral dialects, spoken partly in Italy; (II) Carinthian, spoken mostly in Austria; (III) Upper Carniolan; (IV) Lower Carniolan; (V) Styrian; (VI) Pannonian, spoken partly in Hungary; (VII) Rovte (Figure 1). There are 48 distinct local varieties.

Standard Slovene is constructed of features from various dialects and historical stages of Slovene and does not correspond exactly to any one dialect. Even in the capital, Ljubljana, everyday speech differs in fundamental ways from the standard; compare standard: *kaj mislite*? 'what do you think?' and colloquial: *kva misl̥te*?

Historical Development and Emergence of Literary Language

By the 6th or 7th century A.D., Proto-Slovene was spoken in an area bounded by the Tagliamento River, the Gulf of Trieste, Linz and the outskirts of Vienna, and the southern end of Lake Balaton. The Proto-Slovene speech territory gradually diminished in the medieval period as speakers shifted to Friulian, Italian, German (Standard German), and Hungarian, leaving a core area today consisting of the Republic of Slovenia plus border areas in Italy, Austria, and Hungary.

The earliest surviving documents are the Freising Folia, liturgical texts composed around 1000 A.D., which are among the oldest attestations of any Slavic language. There are a few surviving Slovene documents dating from then until the middle of the 16th century, mostly religious and legal texts. The first printed books in Slovene are Primus Truber's (1508–1586) *Catechismus* (1550) and Jurij Dalmatin's (1547–1598) translation of the Bible (1584), which mark the first attempt at a standard language. Truber modeled the language on the speech of Ljubljana and his native Lower Carniolan. The Counter–Reformation submerged Truber's legacy, while the Protestants developed a regional literary language in the northeast.

Until the 19th century, Slovene remained secondary to the state language, German (Standard German), and, regionally, Italian and Hungarian. Modern standard Slovene dates to Jernej Kopitar's 1809 grammar, the prestige of which was elevated by the poet France Prešeren (1800–1849) and the intellectual circle around Sigismund Zois (1747–1819). The orthographic system essentially as it is found today

Figure 1 Map of Slovene dialects. Roman numerals indicating local speech varieties are referenced in Greenberg (2000).

was codified in Maks Pleteršnik's Slovene–German Dictionary (1894–95).

Political Issues and Language Maintenance

After the incorporation of the Slovene speech territory (minus border regions in Austria, Italy, and Hungary) into the Kingdom of Serbs, Croats and Slovenes in 1918 (renamed Yugoslavia in 1929), Slovene now became subordinate to Serbo-Croatian, the *de facto* lingua franca of the Yugoslav state. The legal status of Slovene was raised after World War II. Its rights as an official language were reaffirmed in the 1974 Yugoslav Constitution. In reality, the status of Slovene remained unfavorable with respect to Serbo-Croatian, an issue that contributed to Slovene dissatisfaction with Yugoslavia and was resolved with the 1991 Slovene secession from that state.

Slovenes continue to be concerned with language rights among their minorities in Italy, Austria, and Hungary, where they have attempted to encourage the respective governments to accord language rights and allow Slovene-language media and education.

Slovene became one of the official languages of the European Union with the 2004 accession.

Phonology

Writing System

Slovene is written in modified Roman letters, with diacritic marks for sounds not represented by the inherited alphabet (see Table 1). Several other letters are sanctioned in standard orthography to render direct citation of foreign words, viz., *Ç*, *ç*; *Ć*, *ć*; *Đ*, *đ*; *Q*, *q*; *Ś*, *ś*; *X*, *x*; *Y*, *y*; *Ź*, *ź*; *Ż*, *ż*.

Vowel System

See Table 2. *i*, *e*, *ɛ*, *a*, *ɔ*, *o*, *u* occur in long stressed syllables, while stressed *ə* is always short (*pes* [pə̀s] 'dog'). In unstressed syllables the distinctions between *e–ɛ* and *o–ɔ* are neutralized to *ɛ* and *ɔ* respectively: *človek* [tʃlə̀ːvɛk] 'person-NOM-sing', *človeka* [tʃlɔvɛ̗́ːka] 'person-GEN-sing'; *potok* [pə̀ːtɔk] 'stream-NOM-sing,' *potoka* [pɔtɔ̗́ːka] 'stream-GEN-sing.' The grapheme *r* between consonants represents a sequence of *ə* + *r*, e.g., *vrt* [vərt] 'garden,' *srce* [sərce] 'heart.'

Word Prosody

Standard Slovene pronunciation allows two accentual norms, one with pitch accent (characteristic of the Carniolan dialects), the other by stress and vowel

Table 1 The Slovene alphabet

Upper case	*Lower case*	*Pronunciation (IPA values where significantly different than English)*
A	a	[a]
B	b	
C	c	[ts]
Č	č	[tʃ]
D	d	
E	e	corresponds to tense and lax e-vowels or schwa (see vowel chart)
F	f	
G	g	
H	h	[x]
I	i	[i]
J	j	[y]
K	k	
L	l	see explanation under Consonants
M	m	
N	n	
O	o	corresponds to tense and lax o-vowels (see vowel chart)
P	p	
R	r	tapped or trilled r
S	s	
Š	š	[ʃ]
T	t	
U	u	[u]
V	v	[w] before a consonant or in word-final position
Z	z	
Ž	ž	[ʒ] as the s in pleasure

Table 2 Standard Slovene vowel phonemes

	Front	*Central*	*Back*
High	i		u
Tense (high-mid)	e	ə	o
Lax (low-mid)	ɛ		ɔ
Low		a

Lateral			l		
Trill/tap			r		
Glides		v [w]		j	

length. In the pitch accent system, any long-stressed syllable – almost always only one per accented word – is characterized by either a low rising tone or a high falling tone. Accented words (i.e., not unstressed particles, prepositions, conjunctions, and some pronouns) that lack a long-stressed vowel are short stressed (phonetically high falling) on the final syllable, for example, *brati* [brá:ti] 'to read' (low rising), *brat* [brà:t] 'to go read' (high falling), *brat* [bràt] 'brother' (short), *poskòk* 'hop' (short).

Stress patterns are morphophonemic in that each morpheme carries an underlying prosodic marker and the concatenation of morphemes to form words determines realization of the placement and identity of the pitch and quantity. The realization of these concatenation rules is that paradigms are characterized either by fixed or by mobile stress patterns, e.g., fixed: *mesto* [mé:sto] 'town-NOM/ACC-sing'–*mesta* [mé:sta] 'town-GEN-sing'–*mestu* [mé:stu] 'town-DAT-sing'; mobile: *meso* [mesò:] 'meat-NOM/ACC-sing'–*mesa* [mesà:] 'meat-GEN-sing'–*mesu* [mé:su] 'meat-DAT-sing.'

Consonant System

See Table 3. *V* is pronounced as English *v* only when it precedes a vowel; otherwise, it is pronounced similarly to *w*: *cerkve* 'church-GEN-sing,' *cerkev* [-kəw] 'church-NOM-sing'; *vrag* [wrak] 'devil'; *navkreber* [-wk-] 'uphill.' *L* is usually pronounced as *w* in word-final position and before a consonant (except in some morphologically conditioned environments, where it is pronounced as [l]): *vedela* 'she knew,' *vedel* [-dew] 'he knew'; *poznavalec* [-ləc] 'connoisseur-NOM-sing,' *poznavalca* [-wca] 'connoisseur-GEN-sing.'

Morphology

Slovene is an inflecting language. Nouns, pronouns, adjectives agree in case, number, and gender. The cases are nominative, accusative, genitive, dative, locative, and instrumental, the last two occurring obligatorily with prepositions. In addition to plural and singular, Slovene has distinct forms for dual. The genders are feminine, masculine, and neuter.

In the standard language masculine adjectives in the nominative and accusative mark the definite article, e.g., *grd obraz* '(an) ugly face,' *grdi obraz* 'the ugly face.' In the colloquial language a definite article has developed from a demonstrative pronoun (in all genders and numbers): *grd* 'ugly' (generic or indefinite), *ta grd* 'the ugly (one).' An indefinite article, also characteristic of colloquial speech, has developed from the numeral 'one' (*eden*), e.g., *ena grda faca* 'an ugly face/guy.'

The present tense of the verb distinguishes person and number. Pronouns are normally dropped unless the subject is emphasized or reference is switched. Second person plural is used also as an honorific for a single addressee.

Table 4 Singular ADJ + noun

Case	*Feminine*	*Masculine*	*Neuter*
Nominative	lepa hiša 'beautiful house'	lep(i) hrib 'beautiful hill, mountain'	lepo mesto 'beautiful town'
Accusative	lepo hišo	lep(i) hrib	lepo mesto
Genitive	lepe hiše	lepega hriba	lepega mesta
Dative	lepi hiši	lepemu hribu	lepemu mestu
Locative	(pri) lepi hiši	(pri) lepem hribu	(pri) lepem mestu
Instrumental	(z) lepo hišo	(z) lepim hribom	(z) lepim mestom

Table 5 Plural ADJ + noun

Case	*Feminine*	*Masculine*	*Neuter*
Nominative	lepe hiše	lepi hribi	lepa mesta
Accusative	lepe hiše	lepe hribe	lepa mesta
Genitive	lepih hiš	lepih hribov	lepih mest
Dative	lepim hišam	lepim hribom	lepim mestom
Locative	(pri) lepih hišah	(pri) lepih hribih	(pri) lepih mestih
Instrumental	(z) lepimi hišami	(z) lepimi hribi	(z) lepimi mesti

Verbs distinguish imperfective and perfective aspect, in general, incomplete vs. completed action. Unprefixed verbs are usually imperfective (*pisati* 'to write') or bi-aspectual (*nesti* 'to carry'). Prefixation creates additional, primarily perfective meanings, such as *podpisati* 'to sign (e.g., a document),' *odnesti* 'to carry something away.' Imperfectives are derived from these prefixed forms by suffixation and sometimes also vowel gradation, e.g., *podpisovati* 'to sign repeatedly, to be in the process of signing,' *odnašati* 'to carry away repeatedly, to be in the process of carrying away.'

Noun and Adjective Inflection

See Tables 4–6.

Verb Inflection

The present tense declension marks person and number. Past and future tenses are constructed of an auxiliary (*sem* = past, *bom* = FUT), conjugated as in the present tense, plus a past participle marked for gender and number, e.g., *sem delal* 'I worked-MASC-sing,' *bom delala* 'I shall work-FEM-sing.' The conditional is formed with an invariant particle *bi*, e.g., *bi delali* 'we/you all/they would work' (see Table 7).

Table 6 Dua ADJ + noun

Case	*Feminine*	*Masculine*	*Neuter*
Nominative, Accusative	lepi hiši	lepa hriba	lepi mesti
Genitive	lepih hiš	lepih hribov	lepih mest
Locative	(pri) lepih hišah	(pri) lepih hribih	(pri) lepih mestih
Dative, Instrumental	lepima hišama	lepima hriboma	lepima mestoma

Table 7 Present-tense inflection

	Singular	*Plural*	*Dual*
1	vozi-m '(I) drive'	vozi-mo	vozi-va
2	vozi-š	vozi-te	vozi-ta
3	vozi	vozi-jo	vozi-ta

Syntax

Word Order

Neutral word order (1) is SVO, but the order may be rearranged depending on emphasis, with either the object moving to the beginning (2) or the subject to the end of the sentence (3).

(1) *Miran* *je*
Miran-NOM-sing 3-sing-AUX
kupil *kruh*
bought-MASC-sing bread.ACC
'Miran bought bread'

(2) *Kruh* *je* *kupil*
bread.ACC 3-sing-AUX bought-MASC-sing
'He bought **bread**'/'It was bread that he bought'

(3) *Kruh* *je* *kupil*
bread.ACC 3-sing-AUX bought-MASC-sing
Miran
Miran-NOM-sing
'**Miran** bought bread'/'It was Miran who bought bread'

In noun phrases the order is DEM + NUM + ADV + ADJ + noun, where all but the ADV agree in case, number and gender:

(4) *Tisti* *dve* *prav*
those-DEM-NOM-DU-FEM two-NOM-DU-FEM quite-ADV
brihtni *punčki*
bright-NOM-DU-FEM girls-NOM-DU-FEM
'these two quite bright girls ....'

Clitics

Clitic elements, in accord with Wackernagel's Law, follow directly after the first accented word or noun phrase in the main clause:

(5) *Trudili* *smo*
try-IMPERF-PP-MASC-PL AUX-1-PL
se *jo* *razumeti*
REFL-PART PRO-3-sing-ACC-FEM understand-INF
'we were trying to understand her'

Subordinate clauses are typically introduced by *da* 'that,' *ki / kateri* 'which,' *ker* 'because,' *ko(t)* 'as,' *če* 'if':

(6) *Prepričana* *sem,* *da* *je*
convinced-FEM-sing be-1-sing that be-3-sing
tvoj *računalnik* *zastarel*
your-MASC-sing-nom comp-MASC-sing-NOM superannuated-MASC-sing-NOM
'I'm convinced that your computer is obsolete'

(7) *Pazi,* *ker* *te*
watch out-IMP-2-sing because PRO-2-sing-ACC
bo *avto* *povozil*
FUT-AUX-3-SG car-ACC-SG run over-PP-MASC-SG
'watch out or the car will run you over'

Lexicon

Historical influences on Slovene have come from Friulian, German (Standard German) (especially the Bavarian and Tyrolean dialects), Hungarian and Croatian (Serbo-Croatian), as well as Venetian Italian (Venetian), Dalmatian and Istrian Romance. A number of languages, including Illyrian and continental Celtic, may have made up substrata to Proto-Slovene (or, more likely, to the Romance dialects that preceded it) and are recognizable as trace elements in the vocabulary, e.g., from Celtic *Karavanke* 'Karawanken Alps,' *Kranj(ska)* 'Carniola.' German (Standard German) and English are the source of most contemporary loans, though these are officially deprecated in favor of native formations, which are increasingly accepted in everyday speech, e.g., *zgoščenka* 'compact disk' from *zgostiti* 'to make compact,' replacing *cedejka*. The youngest generation uses English freely, e.g., *ful dober* 'really good' (from Eng. *full*).

Slovenia: Language Situation

J Orešnik, University of Ljubljana, Ljubljana, Slovenia

© 2006 Elsevier Ltd. All rights reserved.

Slovenian, or Slovene, is the national language of the Republic of Slovenia. Slovenian territory was part of the Hapsburg Empire for centuries before 1918 and part of what was commonly called Yugoslavia between 1918 and 1991. In 1991 Slovenia became an independent republic with a parliamentary democracy. Slovenia is situated on the 'sunny' side of the Alps, bordered by Italy, Austria, Hungary, and Croatia, with a small coastline on the Adriatic Sea. Its area is approximately 20 000 km^2 (7800 mi^2), and its capital is Ljubljana.

The population of 1 964 000 is ethnically 88% Slovenian, and there are Slovenian minorities in Italy (84 000), Austria (40 000), Hungary (6000), and Croatia (approximately 20 000), as well as in diaspora (400 000–500 000). Of the autochthonous

Lexicon

Historical influences on Slovene have come from Friulian, German (Standard German) (especially the Bavarian and Tyrolean dialects), Hungarian and Croatian (Serbo-Croatian), as well as Venetian Italian (Venetian), Dalmatian and Istrian Romance. A number of languages, including Illyrian and continental Celtic, may have made up substrata to Proto-Slovene (or, more likely, to the Romance dialects that preceded it) and are recognizable as trace elements in the vocabulary, e.g., from Celtic *Karavanke* 'Karawanken Alps,' *Kranj(ska)* 'Carniola.' German (Standard German) and English are the source of most contemporary loans, though these are officially deprecated in favor of native formations, which are increasingly accepted in everyday speech, e.g., *zgoščenka* 'compact disk' from *zgostiti* 'to make compact,' replacing *cedejka*. The youngest generation uses English freely, e.g., *ful dober* 'really good' (from Eng. *full*).

Slovenia: Language Situation

J Orešnik, University of Ljubljana, Ljubljana, Slovenia

© 2006 Elsevier Ltd. All rights reserved.

Slovenian, or Slovene, is the national language of the Republic of Slovenia. Slovenian territory was part of the Hapsburg Empire for centuries before 1918 and part of what was commonly called Yugoslavia between 1918 and 1991. In 1991 Slovenia became an independent republic with a parliamentary democracy. Slovenia is situated on the 'sunny' side of the Alps, bordered by Italy, Austria, Hungary, and Croatia, with a small coastline on the Adriatic Sea. Its area is approximately 20 000 km^2 (7800 mi^2), and its capital is Ljubljana.

The population of 1 964 000 is ethnically 88% Slovenian, and there are Slovenian minorities in Italy (84 000), Austria (40 000), Hungary (6000), and Croatia (approximately 20 000), as well as in diaspora (400 000–500 000). Of the autochthonous

minorities in Slovenia, Hungarians (6250) and Italians (2260) enjoy substantial minority rights, whereas the Romany (6000) and Germans/Austrians (680) are not equally represented.

Standardization of Slovenian has proceeded gradually since the beginnings of continuous attestation of the language in the mid-16th century. The language has used the Latin alphabet with three additional letters – č, š, ž – since the mid-19th century. Milestones in the standardization consist of grammars (the first published in 1584) and dictionaries (the monolingual dictionary published 1970–1991, 93 000 headwords), including (repeatedly since 1899) orthographic-and-orthoepic dictionaries and two etymological dictionaries. The principal grammar of Contemporary Standard Slovenian is Toporišič (4th augmented edn., 2000), and Herrity has written a Slovene grammar in English 2000.

Until the end of the 18th century the (preserved) texts were mostly religious. Slovenian literature reached an early peak in the poetry of France Prešeren (1800–1849). In the 19th century and thereafter, Slovenian gradually expanded into all spheres of communication, especially after 1918; the emancipation in 1991 even brought about the use of Slovenian in the military and in diplomacy. Currently, there is a self-imposed nonuse of Slovenian in scholarly publications of the natural sciences, a circumstance that diminishes the prestige of the language in the eyes of its users. Slovenian was most influenced by German (German, Standard and dialects), Serbo–Croatian, and now English; in the latter half of the 19th century the German impact was counterbalanced by conscious Slavization.

Scholarly work on Slovenian has been conducted since the 19th century – first at the Austrian universities of Vienna and Graz, since 1919 at the University of Ljubljana, and since 1975, also at the University of Maribor. Initially, the investigations concentrated on the history and prehistory of the language (and dialectology); since the 1960s even descriptive studies have been in full bloom (including generative grammar) and, in addition, aspects of applied linguistics. Some prominent names in Slovenian language studies include Jernej Kopitar (1780–1844), Franz Miklosich (1813–1891), Stanislav Škrabec (1844–1918), Vatroslav Oblak (1864–1896), Fran Ramovš (1890–1952), and Jože Toporišič (b. 1926).

An important field of activity is Slovenian for foreigners; summer courses in Contemporary Standard Slovenian for foreigners are offered at the University of Ljubljana.

Slovenian Lexicography

B Lönneker, Universität Hamburg, Hamburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

After the standardization of the Slovenian language in the 19th century, the seminal *Slovenian-German dictionary*, containing 110,000 headwords (Pleteršnik, 1894–1895) as well as an orthographic manual combining rules with a monolingual dictionary (Levec, 1899), was compiled.

The Institute of Slovenian Language (ISL), the first Slovenian institution that could coordinate extensive lexicographic work, was created after World War II. The institute, hosted by the Scientific Research Center of the Slovenian Academy of Sciences and Arts, prepares a wide range of monolingual dictionaries. After its foundation, it started the preparation of the *Dictionary of standard Slovenian* SSKJ (Bajec *et al.*, 1970–1991), a five-volume dictionary containing more than 107,000 entries and subentries. The line of Slovenian orthographic manuals has been continued by different authors, but the recent sixth *Slovenian orthography* (Toporišič *et al.*, 2001) was compiled by ISL. Its dictionary part contains 130,000 headwords and subentries, including proper names. In addition to etymological, terminological, and historical dictionaries—many of which are already available—a synonym dictionary, a phraseological dictionary, and a valency dictionary as well as a linguistic atlas for Slovenian are expected to be published by ISL in the near future. The project of a new one-volume monolingual dictionary has been transformed into that of a dictionary of neologisms.

The line of Slovenian orthographic manuals has been continued by different authors, but the recent sixth *Slovenian orthography* (Toporišič *et al.*, 2001) was compiled by ISL. Its dictionary part contains 130,000 headwords and subentries, including proper names. In addition to etymological, terminological, and historical dictionaries—many of which are already available—a synonym dictionary, a phraseological dictionary, and a valency dictionary as well as a linguistic atlas for Slovenian are expected to be published by ISL in the near future. The project of a new one-volume monolingual dictionary has been transformed into that of a dictionary of neologisms.

Slovenian monolingual lexicography is vividly discussed in public, for example, in the journals *Slavistična revija, Jezik in slovstvo*, and *Jezikoslovni zapiski*.

The most comprehensive bilingual dictionaries are published by the publishing house DZS. The three largest ones cover the languages German, English, and Italian, with the following main authors, years of most recent edition, and numbers of headwords: Doris Debenjak (2001: German-Slovenian, 123,000; 2003: Slovenian-German, 100,000), Anton Grad (2004: English-Slovenian, 80,000; 2002: Slovenian-English, 45,000), and Sergij Šlenc (2001: Italian-Slovenian, 70,000). These bilingual dictionaries as well as the *Dictionary of standard Slovenian* are available on CD-ROMs produced by the software company Amebis. A corpus-based English–Slovenian dictionary of 120,000 headwords is to appear from DZS in two volumes (2004: A–K, 2006: L–Z).

The two largest Slovenian corpora, FIDA (owned by DZS, Amebis, the Philosophical Faculty of Ljubljana University, and the research institute Jožef Stefan) and Nova beseda (ISL) comprise more than 100 million words each. Web interfaces provide public access to a restricted version of the FIDA corpus and to the full version of Nova beseda. While FIDA contributes mainly to the compilation of bilingual dictionaries at DZS, Nova beseda supports the preparation of monolingual dictionaries at ISL.

Smith, Adam (1723–1790)

J E Joseph, University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

Adam Smith was born in Kirkcaldy, Scotland, in 1723. He studied at the University of Glasgow from 1737 to 1740, concentrating on mathematics and natural philosophy (science), but he was also much influenced by Francis Hutcheson's lectures on moral philosophy. Smith then moved to Balliol College, Oxford, where for the next seven years, according to the biographical account written by Dugald Stewart, he devoted himself to the "study of human nature in all its branches, more particularly of the political history of mankind" (Stewart, 1793). As part of this study he undertook to master the major European languages and literatures, and it was in the area of rhetoric and belles-lettres that he initially undertook private lecturing when he left Oxford for Edinburgh in 1748.

In 1751 Smith was appointed to the Chair of Logic and Rhetoric at the University of Glasgow, and his lectures continued to be mainly about rhetoric and belles-lettres, prefaced with some considerations of psychology. A year later, the Chair of Moral Philosophy fell vacant and he was given it instead. His lectures from this chair over the next 13 years encompassed rhetoric, theology, and ethics, and also 'Justice, Police, Revenue, and Arms,' a conglomeration from which his political economics would eventually develop. In 1759, drawing mainly from his lectures on ethics, he published *The theory of moral sentiments*, the work that established his reputation universally.

Smith's one direct contribution to the linguistic thought of his time is his 'Considerations concerning the first formation of languages, and the different genius of original and compounded languages,' first published in 1761. It would form part of his lectures on rhetoric, but was appended to the *Theory of moral sentiments* starting with the book's third edition of 1767. The essay falls squarely within the line of historical inquiry launched by Condillac's *Essai sur l'origine des connoissances humaines* (1746), though it appears to be reacting more directly to Rousseau's *Discours sur l'origine et les fondemens de l'inégalité*

Slovenian monolingual lexicography is vividly discussed in public, for example, in the journals *Slavistična revija, Jezik in slovstvo*, and *Jezikoslovni zapiski*.

Adam Smith was born in Kirkcaldy, Scotland, in 1723. He studied at the University of Glasgow from 1737 to 1740, concentrating on mathematics and natural philosophy (science), but he was also much influenced by Francis Hutcheson's lectures on moral philosophy. Smith then moved to Balliol College, Oxford, where for the next seven years, according to the biographical account written by Dugald Stewart, he devoted himself to the "study of human nature in all its branches, more particularly of the political history of mankind" (Stewart, 1793). As part of this study he undertook to master the major European languages and literatures, and it was in the area of rhetoric and belles-lettres that he initially undertook private lecturing when he left Oxford for Edinburgh in 1748.

In 1751 Smith was appointed to the Chair of Logic and Rhetoric at the University of Glasgow, and his lectures continued to be mainly about rhetoric and belles-lettres, prefaced with some considerations of psychology. A year later, the Chair of Moral Philosophy fell vacant and he was given it instead. His lectures from this chair over the next 13 years encompassed rhetoric, theology, and ethics, and also 'Justice, Police, Revenue, and Arms,' a conglomeration from which his political economics would eventually develop. In 1759, drawing mainly from his lectures on ethics, he published *The theory of moral sentiments*, the work that established his reputation universally.

Smith's one direct contribution to the linguistic thought of his time is his 'Considerations concerning the first formation of languages, and the different genius of original and compounded languages,' first published in 1761. It would form part of his lectures on rhetoric, but was appended to the *Theory of moral sentiments* starting with the book's third edition of 1767. The essay falls squarely within the line of historical inquiry launched by Condillac's *Essai sur l'origine des connoissances humaines* (1746), though it appears to be reacting more directly to Rousseau's *Discours sur l'origine et les fondemens de l'inégalité*

parmi les hommes (1755), which it cites, and to Girard's *Vrais principes de la langue françoyse* (1747), which in a letter of 1763 Smith said "first set me a thinking upon these subjects."

According to Smith, language began with savages naming things, then extending a name from one thing to another that resembled it. The creation of adjectives to denote the qualities that produced this resemblance involved considerable abstraction and generalization, even more of which was required to produce prepositions, which indicate metaphysically complex relationships between nouns. A more natural procedure for indicating qualities and relationships is to make a slight change in the noun itself – what we now call inflectional morphology – and Smith asserts a basic distinction between 'original' languages, which rely mainly on inflection, and 'compounded' languages (in modern terminology, 'analytic'), which instead use separate words to express qualities and relationships. Verbs similarly began with the impersonal type (e.g., Latin *pluit* 'it is raining'), then when the need came to express the subject, the 'original' way was to mark it morphologically and the 'compounded' way was to express it separately.

Smith ties the move from original to compounded structures to the historical mixture of populations. Greek, he writes, "seems to be, in a great measure, a simple, uncompounded language, formed from the primitive jargon of those wandering savages, the ancient Hellenians and Pelasgians, from whom the Greek nation is said to have been descended" (§37). This historical simplicity is mirrored in the lexicon of the language: "All the words in the Greek language are derived from about three hundred primitives, a plain evidence that the Greeks formed their language almost entirely among themselves, and that when they had occasion for a new word, they were not accustomed, as we are, to borrow it from some foreign language, but to form it, either by composition, or derivation from some other word or words, in their own" (§37). However, the resultant need to form new words through the morphological processes of composition and derivation means that such simplicity as Greek possesses in its lexicon is balanced by compoundedness in its morphological structure. Latin, in contrast, "is a composition of the Greek and of the ancient Tuscan languages" (§38), a historical make-up that Smith sees as being directly reflected in the compounded structure of the Latin lexicon, while "Its declensions and conjugations accordingly are much less complex than those of the Greek" (§38). French and Italian represent a further stage of compoundedness from that of Latin, and English a still further one, being "compounded of the French and the ancient Saxon languages" (§40).

"In general," he writes, "it may be laid down for a maxim, that the more simple any language is in its composition, the more complex it must be in its declensions and conjugations; and, on the contrary, the more simple it is in its declensions and conjugations, the more complex it must be in its composition" (§36). Over time there are ever fewer original languages and ever more compounded ones, hence the trend away from the highly inflected classical languages toward the simpler morphology (but complex lexica and fixed syntax) of modern tongues. Smith likens this to the process by which a machine gets simplified over time from the complex form in which it is first invented, as its users gain greater awareness of how its parts function – but with the difference that, whereas this process leads to the perfecting of machines, it tends toward increasing imperfection in languages, where simplification of structure makes them more prolix, less agreeable to the ear, and less readily susceptible to the play of syntax for poetic and rhetorical purposes.

Early in 1764 Smith left his chair at Glasgow to accompany the Duke of Buccleuch as his tutor on a tour through continental Europe that would last until October 1766. From that time on Smith labored on his *Inquiry into the nature and causes of the wealth of nations*, which was published in 1776 and became the cornerstone of modern economic theory. In Book IV, Chapter 2, he famously writes of how an individual who "intends only his own gain" is "led by an invisible hand to promote" a social "end which was no part of his intention." In recent years this notion of the "invisible hand" has been invoked in historical linguistics to explain how language change can follow consistent, long-term paths that speakers are unaware of. Whether Smith, who died in 1790, would have endorsed the transfer of this metaphor from economy to language is unknowable but doubtful, since he did not see change in a language as representing any kind of progress for the interests of those who speak it, but enacting a very different kind of structural economy in which a shift from simplicity toward compoundedness follows necessarily from the movement of populations, and provokes an equal and opposite shift within another area of language structure.

Smith, Henry Lee (1913–1972)

A Sacknovitz, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Henry Lee Smith, Jr., is best known for his contributions to the fields of phonology/morphology, literacy, and foreign language teaching. Specifically, Smith introduced the concept of the morphophone, a structural unit between phoneme and morpheme. Smith instructed teachers to create beginning reading materials that concentrated on the association between graphs, one or more letters used to represent a single morphophone, and the morphophone itself. Smith also designed materials for foreign language teaching, many of which are still in use, for the U.S. Army and the Foreign Service Institute (FSI) School of Language and Linguistics (later the School of Languages), which he cofounded.

Smith was born on July 11, 1913, in New Jersey. He received his Bachelor's Degree summa cum laude, Phi Beta Kappa, from Princeton University in 1935. He continued his studies at Princeton, from which he received his M.A. in 1937 and his Ph.D. in Oriental languages and literature in 1938. He was named a Charlotte Elizabeth Procter Fellow at Princeton in 1937–1938. From 1938 to 1940, he lectured at Barnard College, Columbia University, before accepting a two-year appointment as an English instructor at Brown University. From 1942 to 1946, Smith produced manuals, dictionaries, recordings, and phrase books for 22 foreign languages for the Intensive Language Program of the U.S. Armed Forces Institute. In 1946, Smith joined the Department of State and became Assistant Director of the FSI and cofounder of the FSI School of Language and Linguistics, Washington, D.C., in 1946. Appointed professor of languages in 1952, he served as dean of the school in 1955–1956. Smith then went on to cofound and serve as chairman of the Department of Anthropology and Linguistics at the then University of Buffalo (now SUNY-Buffalo) with George L. Trager in 1956. He served as chairman of the Department of Anthropology there from 1964 to 1965 and as director of the Program in Linguistics from 1967 to 1968, before resigning to continue as a full-time professor of Linguistics and English at that same university.

Smith's research in structuralist linguistics was a data-oriented system of analysis focused on using native informants. Smith proposed a series of conclusions about English sounds and structure, many of which can be found in *An outline of English structure*, which he co-authored with George Trager in 1951 (revised in 1957) and which is considered a foundational work in linguistic analysis. In this work, Trager and Smith present a tripartite, 36 vocalic system consisting of nine simple vowel phonemes /i, e, æ, ɨ, ə, a, u, ɔ, o/, which can each combine with each of the three semivowel phonemes /y, w, h/ to form 27 complex vowel nuclei. Although this system is not widely used, it once competed with the IPA system and is the system that William Labov uses, with slight modifications, in his variationist research.

Smith also spent a considerable amount of time thinking and writing about the concept of the morphophone, the basic unit of the morpheme, which Sustakoski, in a foreword to Smith (1968), predicted would be considered as important in the history of linguistics as the clarification of the phoneme. This concept was introduced in Trager and Smith (1951) and was further developed in such publications as 'The concept of the morphophone' (1967), *English morphophonics: implications for the teaching of literacy* (1968), and 'The morphophone and English dialects' (1972). The morphophone, as defined by Smith (1972), was a "'holding company' or 'super family' of different phonemes which are *noncontrasting in the same word*" but also are "a *unit* of the language *as a whole* which, *as a unit*, furnishes the basis for 'higher order' or 'higher level' *contrasts*." To put it in technical language, the morphophone is the *basic unit* of the morpheme, and morphophones are *expressed* by phonemes. Smith claimed that the level of the morphophone was the level at which speakers calibrated equivalence between different phonemes in what they hear as the same words. Contrasts in vowel

Henry Lee Smith, Jr., is best known for his contributions to the fields of phonology/morphology, literacy, and foreign language teaching. Specifically, Smith introduced the concept of the morphophone, a structural unit between phoneme and morpheme. Smith instructed teachers to create beginning reading materials that concentrated on the association between graphs, one or more letters used to represent a single morphophone, and the morphophone itself. Smith also designed materials for foreign language teaching, many of which are still in use, for the U.S. Army and the Foreign Service Institute (FSI) School of Language and Linguistics (later the School of Languages), which he cofounded.

Smith was born on July 11, 1913, in New Jersey. He received his Bachelor's Degree summa cum laude, Phi Beta Kappa, from Princeton University in 1935. He continued his studies at Princeton, from which he received his M.A. in 1937 and his Ph.D. in Oriental languages and literature in 1938. He was named a Charlotte Elizabeth Procter Fellow at Princeton in 1937–1938. From 1938 to 1940, he lectured at Barnard College, Columbia University, before accepting a two-year appointment as an English instructor at Brown University. From 1942 to 1946, Smith produced manuals, dictionaries, recordings, and phrase books for 22 foreign languages for the Intensive Language Program of the U.S. Armed Forces Institute. In 1946, Smith joined the Department of State and became Assistant Director of the FSI and cofounder of the FSI School of Language and Linguistics, Washington, D.C., in 1946. Appointed professor of languages in 1952, he served as dean of the school in 1955–1956. Smith then went on to cofound and serve as chairman of the Department of Anthropology and Linguistics at the then University of Buffalo (now SUNY-Buffalo) with George L. Trager in 1956. He served as chairman of the Department of Anthropology there from 1964 to 1965 and as director of the Program in Linguistics from 1967 to 1968, before resigning to continue as a full-time professor of Linguistics and English at that same university.

Smith's research in structuralist linguistics was a data-oriented system of analysis focused on using native informants. Smith proposed a series of conclusions about English sounds and structure, many of which can be found in *An outline of English structure*, which he co-authored with George Trager in 1951 (revised in 1957) and which is considered a foundational work in linguistic analysis. In this work, Trager and Smith present a tripartite, 36 vocalic system consisting of nine simple vowel phonemes /i, e, æ, ɨ, ə, a, u, ɔ, o/, which can each combine with each of the three semivowel phonemes /y, w, h/ to form 27 complex vowel nuclei. Although this system is not widely used, it once competed with the IPA system and is the system that William Labov uses, with slight modifications, in his variationist research.

Smith also spent a considerable amount of time thinking and writing about the concept of the morphophone, the basic unit of the morpheme, which Sustakoski, in a foreword to Smith (1968), predicted would be considered as important in the history of linguistics as the clarification of the phoneme. This concept was introduced in Trager and Smith (1951) and was further developed in such publications as 'The concept of the morphophone' (1967), *English morphophonics: implications for the teaching of literacy* (1968), and 'The morphophone and English dialects' (1972). The morphophone, as defined by Smith (1972), was a "'holding company' or 'super family' of different phonemes which are *noncontrasting in the same word*" but also are "a *unit* of the language *as a whole* which, *as a unit*, furnishes the basis for 'higher order' or 'higher level' *contrasts*." To put it in technical language, the morphophone is the *basic unit* of the morpheme, and morphophones are *expressed* by phonemes. Smith claimed that the level of the morphophone was the level at which speakers calibrated equivalence between different phonemes in what they hear as the same words. Contrasts in vowel

phonemes that occurred in pristine environments, or, in English, monosyllabic words ending in /p/, /t/, /k/, were primary contrasts, requiring a separate morphophone unit for each contrast. Phonemes that make these contrasts were the principal variants of the morphophone unit, each of which constituted the pure variants of each morphophone unit. Secondary contrasts occurred when different phonemic expressions were analyzed as the principal covariants of the same unit, but did not occur in pristine environments. Tertiary contrasts occurred when phonemes making the contrasts never occurred in pristine environments, are assignable within the idiolect to two morphophone units, and are in free variation with those constituting the principal variants of each of the two units. Dialects differ in their diamorphophonic selections, or the selection of different morphophone units as units that are noncontrasting in the same words. Smith felt that one could objectively distinguish between dialects and languages based on whether calibration between different forms of morphonones was evident (dialects of same language) or not (two separate languages).

For Smith, the morphophone was a useful tool for language education. Smith claimed that the current writing system was based on the graphic representation of morphophone units rather than phonemes. Readers respond to graphic symbolizations with the phonemic expressions of the morphophones from their dialect or idiolect. In a 1954 lecture at Harvard University, 'Linguistic science and the teaching of English' (published in 1956), Smith stated that language educators should systematically teach the relationship between sound and letter. In addition, Smith co-authored *The linguistic readers* (1963–1967), materials for beginning learners, and *A linguistic approach to English* (1964 and 1965), designed for high school students, both of which incorporate the concept of morphophone.

In general, Smith felt that language educators needed to learn more about linguistics. He stressed that teachers needed to understand that students' variable pronunciations were not incorrect pronunciations. He also emphasized that teachers should never make a child feel inadequate because of his or her variable pronunciation.

Smith also hoped to teach the general public about linguistics. He prepared and appeared on such programs as 'Where Are You From?' on WOR New York from 1939 to 1941, in which he asked participants to pronounce words and would try to determine their dialects; a 13-film series titled 'Language and Linguistics' in 1959; 'Meet the Professor'; and 'Speaking of Ideas,' a weekly program airing on WGR Buffalo that he moderated from 1961 to 1964. He also appeared on the television quiz shows 'What's My Line?' and 'I've Got a Secret.'

For the last years of his life, Smith was working on what he called aspectualism, a descriptive analysis of English that relied on real world events. This system expanded a tripartite approach of phonology, morphology, and semology to a total of 27 levels, or aspects. His final results were never published since Smith died suddenly of a heart attack on December 13, 1972, after speaking to a civic group about English dialects. He was survived by his wife, Virginia von Wodtke Smith, who died in 1987, and four children, Heather Kleiner, Marshall, Randolph, and Letitia.

Social Aspects of Pragmatics

K Rajagopalan, State University at Campinas, Campinas, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Introduction

It might seem somewhat strange to talk of 'the social aspects of pragmatics' because the very choice of such a topic might lead a newcomer to the field to think that, strictly speaking, there is nothing social about pragmatics. That such an inference is perfectly in order may be verified by comparing the expression to an analogous one like 'the economic aspects of the AIDS pandemic' where clearly no one is suggesting that economics is of the very essence as far as AIDS is concerned. Does it at all make sense, one might ask, to conceive of pragmatics in any terms other than social? Alternatively, is it not pleonastic to speak of the social aspects of pragmatics, given that, no matter how you define the field of research called linguistic pragmatics, the social dimension of language will – or should, if it is to remain faithful to its object of study – turn out to be constitutive of it, rather than something added on to it subsequently, say, by way of an afterthought? As Koyama (1997: 1) put it, "[. . .] a pragmatic theory is evidently a linguistic and social theory at once."

Furthermore, if it is granted that pragmatics addresses issues relating to the use of language, as most scholars would agree it does, one might equally wonder how one can sensibly approach such issues except by first recognizing their social embeddedness. Finally, isn't language itself, as Dummett (1975: 135) aptly put it, "something *essentially social*, a practice in which many people engage" (italics added)? Or isn't it essentially "dialogic," as Bakhtin (1981) forcefully argued, thus, to quote Dentith (1995: 91), "radically socializ[ing]" the way the speaking subject is theorized? Mey (1985: 11) goes straight to the heart of the matter when he says:

> We cannot describe language and its use outside the context of that use, viz. the society in which language is used. To start out either with a definition of language (which one?), and then define society (what kind of?), or the other way around, will only lead to endeavors (as frantic as they are makeshift) to paste together what never should have been separated in the first place.

Neglect of Society in Language Studies

But the fact remains that many scholars have traditionally preferred to theorize language in complete disregard for its social setting. There has been a strong tendency among linguists to reify language and view it as a purely mental phenomenon and, as such, the attribute of a single individual existing, as it were, in an idyllically pre-social, Adamic or pre-Fall state. The following remark by Whitney (1827–1894) is typical of a research orientation that dominated most of the thinking on the nature of language in the 19th and 20th centuries.

> There can be asked respecting language no other question of a more elementary and at the same time of a more fundamentally important character than this: how is language obtained by us? How does each speaking individual become possessed of his speech? Its true answer involves and determines well-nigh the whole of linguistic philosophy (Whitney, 1875 [1979]: 7).

Notice that the whole emphasis is on the individual acquiring his/her linguistic skills – the initial mention of "us" gives way, with no justification or apology whatsoever, to "each speaking individual" now being considered severally rather than collectively. The fact that, for a language to be said to exist in any minimally meaningful sense of the word there must be at least two speakers who use that language to communicate to each other, is treated as being of secondary or marginal interest. Instead, all attention is directed at the single individual and his/her knowledge of the language in question. This is all the more intriguing because, as has been pointed out (cf. Andresen, 1990), Whitney belonged to a period in the history of the United States when scholarly research on language was intimately tied to a wider agenda of national self-affirmation, so that, far from being considered an autonomous entity, language was seen as a national symbol, hence approached from an eminently political perspective.

Linguistics and the Focus on the Individual Speaker

In focusing on the individual speaker, Whitney was anticipating what was to become a central tendency in linguistics as the discipline consolidated itself in the first half of the 20th century. When in the mid-1950s, Noam Chomsky revolutionized linguistics with his radically new approach, the centerpiece of his theorizing was, true to this long tradition of relegating the social to the margins, an idealized speaker-hearer, that is to say, the two clearly distinguishable ends of a minimal communicative event (Saussure's twin "talking heads") fused into one. Society or the social embeddedness of the speaker was, in Chomsky's view, a fact of no great consequence. Here is how he put it: "As for the fact that the rules of language are 'public rules,' this is, indeed, a contingent fact." (Chomsky, 1975: 71). Society is viewed as nothing but the

backdrop against which the individual is to be singled out and focused on. The 'social context' is then equated with 'extra-linguistic context' (Fetzer and Akman, 2002: 395), thus giving short shrift to the fundamental role played by society in constituting a language. Such principled neglect of society has been justified in the name of 'autonomism' by Frederick Newmeyer, who summed up the guiding spirit of the whole approach in the following words:

> (The advocates of autonomism) approach language as a natural scientist would study a physical phenomenon, that is, by focusing on those of its properties that exist apart from either the beliefs and values of the individual speakers of language or the nature of the society in which the language is spoken (Newmeyer, 1986: 5–6).

Dissident Voices

No doubt, there are important exceptions to the dominant tendency to construct a theory of language around the figure of a single individual. Thus, Hymes warned: "A perspective which treats language only as an attribute of man leaves language as an attribute of men unintelligible" (Hymes, 1973: 60). Writing in much the same vein, Halliday characterized linguistics as a "social semiotic" and insisted that "[a] speaking man does not talk; men talk" (Halliday, 1974: 17). Outside the disciplinary bounds of linguistics, Wittgenstein (1953) had already put forward what is famously known as the 'private language argument': an argument against the very possibility – not empirical, but conceptual – of a language so exclusively private that no one else has access to it. As Itkonen (1996) has forcefully argued, Wittgenstein's argument strikes at the heart of Chomsky's conception of language. So, too, from a completely different perspective, the Russian psychologist Lev Vygotsky (1896–1934) had insisted on the importance of social interaction in the development of cognition, arguing that

> All the higher functions [including voluntary attention, logical memory, and the formation of concepts] originate as actual relationships between individuals (Vygotsky, 1978: 57).

Speaking from a philosophical perspective, Hacker (1988: 171) preferred not to mince matters when he declared:

> The study of language is not a branch of psychology. Little but confusion has stemmed from the supposition that linguists are investigating the nature of the mind, or the mechanisms of understanding.

The Genealogy of the Lone Individual

Given the predominant tendency among linguists to start their inquiry into the nature of language around single speakers and their linguistic competence and only subsequently pan out in order to look at the society of which the individual is an integral part, it is useful to begin by asking why it is that the lone individual occupies such a central place in much of the thinking about language.

The Broader Canvas

It is not all that difficult to track down the origins of modern linguistics' excessive emphasis on the individual speakers and their linguistic competence, in combination with its relative neglect of society which is where, as we have seen, a language can truly be said to exist. As has been argued by a number of scholars (e.g., Hutton, 1996), modern linguistics is a discipline heavily premised on principles that date back to the 19th century. Taylor (1992: 25ff) points out that, some time during the 18th century, the idea of man as a socially inscribed being gave way to that of a uniquely constituted self, based on self-awareness and self-reflection. In Germany, Herder (1744–1803) contributed to the shaping of not only an individual identity, but also of a collective one, modeled on that individual identity (for instance, that of a people or *Volk*), by insisting that the Germans could only aspire to a national identity by being true to themselves and their past and not, say, by aping the French.

Ian Watt (1957, 1996) has painstakingly documented the growth of individualism in the 18th through 19th centuries, as reflected in the literary works of the period. The new sense of realism that swept across Europe during that period was accompanied by the equally new spirit of individualism, and the two together underpinned what one might call the cultural and sociopolitical ethos of the period. Daniel Defoe's *Robinson Crusoe* is a synthesis of that ethos. Modeled on the real life story of a man called Alexander Selkirk, the protagonist of what many literary critics consider the first English novel is the finest example of the glorification of the loner. The importance of Crusoe as a key to the understanding of changing perceptions of the lone individual can only be fully appreciated if we compare him to Faust, Don Juan, and Don Quixote, all originally conjured up between the 16th and the 18th centuries by their respective creators as prototypes of 'anti-individuals' – the first two are burned in hell-fire and the last is publicly mocked and ridiculed. Incidentally, it is also the very same figure of the loner who is glorified when historians of modern philosophy fondly register that René

Descartes, its founding father, experienced a moment of intense inspiration during a dream "in a stove-heated room" when he was serving at Ulm in 1619 (Blackburn, 1994: 100). Linguistics in general and much of early pragmatics is thus wedded to the idea of "the Cartesian autonomous agent" (Kopytko, 2001).

As Watt shows, by the 19th century, this inward-looking and narcissistic individualism had firmly taken hold of the European psyche. The spirit of colonial expansionism that swept across the continent glorified the figure of the loner who braved the elements and conquered distant lands – a Tarzan in the land of apes. The spirit of Enlightenment also took its cue from Descartes and elected the loner as the prototype of the reasoning man in intense meditation, away from the madding crowd, as portrayed in the familiar tale told about Socrates, the Father of Western Philosophy, lost in a philosophical trance while perched on his doorstep before being rudely awakened by a bucketful of cold water tossed at him by Xanthippe, his notoriously cantankerous wife. Radical, navel-gazing forms of individualism have been complicit in the history of European colonialism (cf. Said, 1978) on the one hand, and, on the other, tied up with the very emergence of modern society (Berman, 1971). It is interesting to note in this context that even Freudian psychoanalysis, which otherwise called into question some of the fundamental tenets of modernism, such as the centrality of the all-knowing rational agent, was built around the concept of the lone individual (*see* **Psychoanalysis and Language**). In writings such as *Totem and Taboo* and *Civilization and its Discontents*, Freud took a view of the progress of human civilization (as evolving, according to him, from savagery to monotheism and patriarchy) along essentially the same lines as he considered the child's development to adulthood; thus, Freud became the lightning rod for charges of ethnocentrism, and the accusation that the very idea of Oedipus is "colonialism pursued by other means" (Deleuze and Guattari, 1977: 170).

In thinking about and theorizing about language, the intellectual stance adumbrated in the foregoing paragraphs contributed to the consolidation of the idea that language itself is but the visible manifestation of the reasoning mind. It is not surprising therefore that, to the extent that the human linguistic faculty was seen as a property of man's reasoning mind, language itself was seen as primarily pertaining to the individual speaker-listener and only secondarily and derivatively to the society. Indeed, the centrality accorded to the lone individual underwrites the widespread practice among scholars working in the area of language acquisition of simply taking it for granted that phylogeny follows the same course as ontogeny. The underlying principle may be seen as authorizing the widespread use of biological metaphors such as 'growth', 'decline, 'death', etc., to depict specific moments in the history of an irreducibly social object such as language.

The More Immediate Context

The reason why many pragmaticists have tended to concentrate on the cognitive dimension, often to the total neglect of the social – Steven Davis' 1991 book *Pragmatics: a reader* (Davis, 1991) has an entire section devoted to Psychology and Pragmatics but none whatsoever entitled Sociology and Pragmatics) – has more to do with the way this 'branch of linguistics' developed historically, in spite of claims such as made by the editors of the first of issue of the *Journal of Pragmatics* to the effect that the "science of language use," as it is pursued by contemporary researchers, has "no direct ties with the historical use of the term" (Haberland and Mey, 1977: 1). Originally conceived as part of a general theory of signs, pragmatics is often seen as dealing with those aspects of meaning that cannot be adequately handled by semantics, thus representing, as Tyler (1978: 461) lamented, "a mere appendage of semantics"; alternatively, from the perspective of contemporary generative grammar, pragmatics should be dealt with by syntax, given that a central tendency within this paradigm today is to empty semantics of most or all of its contents, distributing the spoils between the other two components of the old triad (*see* **Syntax-Pragmatics Interface: Overview**). Katz and Fodor (1963) famously delimited the domain of semantics by stipulating that "Linguistic description minus grammar equals semantics," and Gazdar (1979), most likely taking his cue from them, went on to characterize pragmatics as "meaning minus semantics." In other words, pragmatics became the "wastebasket" (Bar-Hillel, 1971) of linguistics and the working motto of linguists became: "When in trouble call it pragmatics and jump!" (Haberland and Mey, 1977: 7) (*see* **Pragmatics: Overview**).

The tripartite division of the theory of signs into syntax, semantics, and pragmatics has led many unwitting scholars to conclude that syntax is the crux, or, if you will, the real hard core of linguistics, with a progressive 'softening up' of rigor and internal coherence as one moves from syntax through semantics to pragmatics. This attitude is spelled out in such remarks as

> Pragmatics, though less so than syntax and semantics, is characterized by a set of central research issues forming a coherent scientific program of linguistic inquiry (ter Meulen, 1978: 439).

The underlying preoccupation in such descriptions of the role of pragmatics seems to be to define the subfield relative to what by implication is treated as its 'meatier' sister subdisciplines. It is as though the scientific credentials of pragmatics could only be established by parading it alongside the other two members of the triad and conceding how miserably it pales in comparison.

On Defining a New Role for Pragmatics

A more liberating view of what pragmatics should concern itself with is taken by Cook when he says:

> Pragmatic philosophy is not, as it is often taken to be, a ready-made technique for analyzing occurring discourse . . .. The subjective, selective, and fundamentally unscientific nature of analysis of language in context should be acknowledged and not disguised by adopting the symbols and signs of more confident (if less exciting) approaches (Cook, 1990: 15).

In fact, a positive development in recent years has been a clearly discernible tendency among leading pragmatists to rethink the very contribution of pragmatics to an understanding of language. Thus McHoul (1997) makes a clarion call for a 'pragrammatology' on the strength of Jacques Derrida's candid admission that "[g]rammatology has always been a sort of pragmatics" (Derrida, 1988: 159), and urges fellow pragmatists to "'deconstruct' all hitherto-existing pragmatics." Verschueren pleads for a sea-change in the way we conceptualize pragmatics, starting with viewing it as "not a layer or component but a perspective" (Verschueren, 1987, 1999a) and argues that "[a] thorough 'ideological' critique of the pragmatic literature is urgently called for" (Verschueren, 1999b: 877).

Mey has been one of the leading scholars in the crusade to openly politicize research in pragmatics, thus initiating what one might refer to as the 'critical turn' in contemporary pragmatics. With hindsight, one may consider the following excerpt as marking a watershed:

> One of the main theses is that our use of language cements the dominant interests of our society, helping to oppress a large segment of the population (Mey, 1985: 16).

For Mey, work done in linguistic pragmatics should go beyond the merely descriptive or explanatory ambitions of mainstream linguistics and embrace transformative or emancipatory goals. The idea of pragmatics as a 'perspective of linguistics' is also forcefully defended by Mey (2001 [1993]).

Not just a perspective *of* linguistics, one may note, but a perspective *on* linguistics. Thus Haberland and Mey (2002: 1672) underscore the urgent need for ensuring that work done in pragmatics is socially relevant, drawing attention to the "society's need for language studies." The rhetorical question posed by the authors (Haberland and Mey, 2002: 1673) when they ask whether pragmatics should be defined "from the inside out" or "from the outside in," "by considering the conditions that make the object possible" may be read as a powerful indictment of the hallowed practice in mainstream linguistics of conceptualizing language by starting with the lone speaker, i.e., starting with what goes on in the mind of the individual speaker and finally paying lip service to the idea that that individual, as it happens, is socially embedded.

The Politics of Pragmatics

The New Orientation

The basic upshot of the discussion in the foregoing section is that research in pragmatics is inescapably caught up in the politics of language and, no less important, in the politics of linguistics. What the recent about-face in pragmatic research – implied in the transition from a component of to a perspective of/on linguistics – really amounts to is a desire on the part of leading researchers to carve out a disciplinary matrix where they no longer have to wait to work on unresolved problems in so-called 'hard core linguistics' (i.e., linguistics where the social question enters as at best an afterthought), but to rethink the very role of society in molding and sustaining language. It is, above all, a desire to free research on language from its time-honored tendency to concentrate on "the language user as an autonomous agent, a kind of linguistic Robinson Crusoe, always reinventing the linguistic wheel" (Mey, 2000: 7).

Interesting Consequences

It is important to point out that a willingness to look at language "from the outside in" rather than "from the inside out" has interesting and often dramatic consequences for the way we identify problems and propose solutions. To begin with, there is a need to recognize that many of the problems we have customarily identified in language are the result of our "inside out" way of conceiving of language. Examples are legion. Consider, for example, the treatment standardly given to the phenomenon linguists have identified as the 'context.' The practice of forcibly isolating naturally occurring utterances in order to study them as mere ordered sequences of words or sentences, or what has been referred to as "context-excluding fact fetishism" (Mey, 2003), is what made the whole concept of context so attractive to begin with and at the same time ever so elusive.

Recent work on context and the whole idea of 'recontextualizing' in order to solve such problems as ambiguity and vagueness (both of which only exist when sentences are focused on in isolation from their contexts) shows that a radically new approach is called for (Scharfstein, 1989; Akman and Bazzanella, 2003) (*see* **Context, Communicative**). Nerlich and Clarke (2001) illustrate one interesting possibility of looking at ambiguity, not as a structural given, but as something that language users purposively exploit to certain communicative ends. Contrary to what theorists of implicature and relevance imagine, these authors contend "that people who engage in conversation do not always strive for rationality and relevance, that they do not always intend words to have one meaning and 'disambiguate' polysemous words automatically in context" (Nerlich and Clarke, 1002: 1) (*see* **Conspicuity**).

The Lure of Cognitivism

Athough, as we have seen, there is today a clearly recognizable move today toward rethinking pragmatics by recognizing the inalienable social nature of language, one should by no means overlook what Haberland and Mey call "a revisionist or reductionist tendency" among certain practitioners, as manifested in the attempts "to revise and 'redo' especially Grice and, to a lesser degree Austin" (Haberland and Mey, 2002: 1674).

Perhaps the best-known attempt at 'revising' Grice is Sperber and Wilson's (1986) work on relevance, aptly described by Levinson (1989: 469) as "an ambitious bid for a paradigm-change in pragmatics" whereby "pragmatics is reduced to a single cognitive principle, a mental reflex, which governs much else besides language use." For Carston (2000: 87), relevance theory brings pragmatics in line with formal linguistics with the only difference that "it is an account of performance mechanisms" (*see* **Relevance Theory**).

There is no doubt either that Austin, too, has been hijacked to fit into the mold of mainstream linguistics. It has been argued (Rajagopalan, 2000) that Searle's intervention has been pivotal in 'domesticating' Austin and revising his thoughts in such a way that they could be incorporated into the formal structure provided by generative grammar in what is referred to as the 'abstract performative hypothesis.' By decontextualizing the individual speech act, i.e., by prying it from its context in order to consider it in isolation as a unit invested with a certain communicative (illocutionary) potential, Searle made it possible for the concept to be smoothly absorbed into the model of syntax being proposed by the advocates of 'generative semantics', inviting such pointed criticisms as:

> There is, to my mind, no escaping the observation that context, which is most proximately and consequentially temporal and sequential, is not like some penthouse to be added after the structure of action has been built out of constitutive intentional, logical, syntactic, semantic and pragmatic/speech-act-theoretic bricks (Schegloff, 1992: 125).

Societal Pragmatics as a Politically Self-conscious Way of Doing Pragmatics

Margaret Thatcher's famous words "There is no such thing as society. There are individual men and women, and there are families" (Thatcher, 1987) were not uttered before an audience of linguists. Yet, her words have important implications for the way we go about setting up priorities in our research in the field of pragmatics. Cognitivism and societalism are not simply two purely theoretical alternatives. Neither is the choice between them simply a matter of attaining adequacy at the descriptive or explanatory levels. The choice between the two is political.

Cognitivism and societalism in pragmatics have their counterparts in political philosophy in individualism and collectivism – which entail conflicting views on the nature of the human being, society, and the relationship between the two. Thatcher's summary dismissal of society has important political connotations. So, too, does the dominant attitude in many mainstream theories in linguistics of relegating the social underpinnings of language to a lesser status.

Thus Mey and Talbot (1988) criticize what they see as "the presumed lack of social consciousness that is inherent in relevance theory." "The important bit here," they note, "is the social anchoring of language use – not, as some would like to have it, the reduction of all society to language use, i.e., to competing discourses."

Conclusion

As one surveys the recent history of intense research in the field of linguistic pragmatics, one cannot but be struck by the perception that, despite great advances made in the direction of recognizing the social nature of language as the key to coming to grips with language in use, there has also been some rearguard maneuvering to suppress the social dimension by privileging the cognitive. The road ahead is thus one paved with political considerations.

Social Class and Status

D F Brown, Howard College, Durban, South Africa

© 2006 Elsevier Ltd. All rights reserved.

The key concepts of social class and status are like most in the social sciences, subject to change in purpose and meaning. Both are rooted in the discipline of sociology, and are central concepts in attempts to describe and explain social inequality and division arising from industrialization, capitalism, and democracy spanning two centuries in industrial and postindustrial societies throughout the world. As to be expected, the major theories differ as to how they define social classes and status groups.

To complicate matters, the concepts of social class and status have been absorbed into linguistic and sociolinguistic theory from different and often conflicting sociological perspectives creating substantial debate. Indeed, some authors would argue that normative sociological concepts have been introduced into linguistic endeavor in an extremely uncritical fashion (Coupland, 2001: 1–26; Williams, 1992; Le Page, 1997).

Since the 1960s, there has been an added interest in the nature of cultural capital, educational credentials, accumulation of knowledge, symbolic systems, and their relationship to social class (Bell, 1974; Habermas, 1987). The investigation of symbolic systems such as language, has in this way contributed to attempts to describe and understand the nature of social class and status. The use of class and status in linguistics, and specifically sociolinguistics, broadens the attempt at understanding society from the socioeconomic base to the super structural and cultural spheres of society. The emergence of sociolinguistics as an area of enquiry coincides with this period.

Common Sense and Class

Social class has its etymological root in the Latin term *classis*, used by census takers to differentiate social strata based on wealth, in order to assess Roman citizens's obligations to military service (Mann, 1983). Within sociological thought, the concept of social class emerged from common sense concepts. For example, the term 'the working class' emerged in English in the early 1800s to describe anyone who worked for a living, as opposed to landlords, who did not have to work and who had a guaranteed income. It slowly shifted its meaning to people who did mainly physical and skilled labor. The common sense use of class, such as in 'lower class' and 'upper class,' are general and relative terms, not always well defined, and still used as such in sociological and sociolinguistic writing. The terminology of social class is, in other words, not exact and is in need of some explanation if we are to get beyond a common sense notion (Williams, 1983). It is necessary to trace the two 'classical' approaches to social class and status, and then to link them to approaches to research on language and society.

Two Approaches to Class as Social Formation

If defining social class presents problems, it is useful for linguists to know which conceptualization within sociology is being drawn on. 'Class as social formation' refers to the development of class in its dual manifestation. A 'class in itself' encapsulates the objective criterion of the structural emergence of class in relation to the means of production. Once a class develops consciousness and self-awareness as a social

The key concepts of social class and status are like most in the social sciences, subject to change in purpose and meaning. Both are rooted in the discipline of sociology, and are central concepts in attempts to describe and explain social inequality and division arising from industrialization, capitalism, and democracy spanning two centuries in industrial and postindustrial societies throughout the world. As to be expected, the major theories differ as to how they define social classes and status groups.

To complicate matters, the concepts of social class and status have been absorbed into linguistic and sociolinguistic theory from different and often conflicting sociological perspectives creating substantial debate. Indeed, some authors would argue that normative sociological concepts have been introduced into linguistic endeavor in an extremely uncritical fashion (Coupland, 2001: 1–26; Williams, 1992; Le Page, 1997).

Since the 1960s, there has been an added interest in the nature of cultural capital, educational credentials, accumulation of knowledge, symbolic systems, and their relationship to social class (Bell, 1974; Habermas, 1987). The investigation of symbolic systems such as language, has in this way contributed to attempts to describe and understand the nature of social class and status. The use of class and status in linguistics, and specifically sociolinguistics, broadens the attempt at understanding society from the socioeconomic base to the super structural and cultural spheres of society. The emergence of sociolinguistics as an area of enquiry coincides with this period.

Common Sense and Class

Social class has its etymological root in the Latin term *classis*, used by census takers to differentiate social strata based on wealth, in order to assess Roman citizens's obligations to military service (Mann, 1983). Within sociological thought, the concept of social class emerged from common sense concepts. For example, the term 'the working class' emerged in English in the early 1800s to describe anyone who worked for a living, as opposed to landlords, who did not have to work and who had a guaranteed income. It slowly shifted its meaning to people who did mainly physical and skilled labor. The common sense use of class, such as in 'lower class' and 'upper class,' are general and relative terms, not always well defined, and still used as such in sociological and sociolinguistic writing. The terminology of social class is, in other words, not exact and is in need of some explanation if we are to get beyond a common sense notion (Williams, 1983). It is necessary to trace the two 'classical' approaches to social class and status, and then to link them to approaches to research on language and society.

Two Approaches to Class as Social Formation

If defining social class presents problems, it is useful for linguists to know which conceptualization within sociology is being drawn on. 'Class as social formation' refers to the development of class in its dual manifestation. A 'class in itself' encapsulates the objective criterion of the structural emergence of class in relation to the means of production. Once a class develops consciousness and self-awareness as a social

group, it becomes a 'class for itself,' as characterized by Marx – the subjective criterion of being a class – and engages with other classes in the furtherance of its own interests. This approach to class as social formation is found in the work of two key theorists in sociology, Karl Marx and Max Weber. These two strands of sociological thought have been elaborated in subsequent generations; their advocates are now described as neo-Marxist and neo-Weberian.

The Marxist Perspective

A Marxist view of social class is based on a subjective notion, with social classes determined by relationships and consciousness. The early Marxist categories of social class, defined the social groups' relationships to the ownership of the means of production. The key ones were: peasantry (small, largely subsistence farmers), lumpen proletariat (unemployed and criminal strata), proletariat (employed working class), petite bourgeoisie (the middle class) and bourgeoisie (the capitalist class). The relationships were defined by exploitation under capitalism, this entailed the process whereby the bourgeoisie benefited from the surplus created by the proletariat.

The social process surrounding the formation and relationships of these classes was for Marx one of intense conflict and struggle; it was central to determining the course of history. For him, the proletariat was the key to social change, and the class that would ultimately bring freedom from capitalist domination. Hence, his notion that the central social conflict under capitalism was between the proletariat and the bourgeoisie. He discussed other classes but did not portray their role as formative.

This was literally a world-dividing perspective on society. Some within the Marxist tradition were partially critical and wished to modify Marx's arguments. For example, while adopting many of Marx's explanations, members of the Frankfurt school in the 1920s, did not view the working class as a key liberating force. In contrast, they sought to explain its fragmentation on the one hand and on the other, its identity with authoritarian forms of thought in the 20th century (Held, 1980).

Marx had little to say about language and symbolic systems and their relationship to class. For him, these were questions about culture and the superstructure of society. A specifically Marxist perspective on language did not emerge until the 1930s, when the Russian author V. N. Volosinov wrote his treatise *Marxism and the philosophy of language* (Volosinov, 1986). This particular work only became generally known in the 1970s through its translation from Russian; written some forty years earlier. It was the first text to look at the relationship between class, semiotic social systems and language from a Marxist perspective. The empirical interest in the text is firstly a stylistic question on the nature of reported speech and then on questions of discourse.

The Weberian Perspective

Max Weber's perspective of class as a social formation differs in important respects. In a key paper, 'Class, status and party,' he added the concepts of status and political party, social groupings that cut across and create social cleavages in social classes. He gave examples of religious and ethnic associations forming status groups, with strong ties of identity and subjective perceptions of community. Weber redefined the concept of status, and gave it equal importance to class as a motivating feature of conflict and change in society. As a result, the combined power of class, status, and party were what determined historical and social change in an industrializing and bureaucratizing world; social class alone was not the sole determinant for Weber. In addition, he emphasized market and consumption, and saw property or lack of property, as a key to defining class. In the 1920s, Weber saw the future unfolding in what he described as the 'iron cage of capitalism,' the inexorable continuation of class, status group, and party conflicts; and that social mobility was one of the few factors that could temper the consequences of such conflict.

Weber argued that neither class nor status were dominant; instead, he asserted that the one that prevailed at any time depended on economic circumstances. While status group competition predominated during periods of relative stability, class conflict emerged when rapid or extensive economic and technological change took place. From this Weberian perspective, power did not always lie with the dominant social groupings. Social closure, a mechanism for excluding other groups and classes from decision-making positions, was for Weber a means by which status groups or classes organized their conflict.

Both Marxist and Weberian approaches viewed society in terms of conflicting human interests, and held that the nature of class composition, relationships, status, political party, and property constantly changed. (Weber redefined status and added political party and property, and emphasized that power does not always lie with dominant social groupings.) Weber in essence offered a critique of Marx's theory, in that he extended the concept of social class. For linguistics, the significance of social class as a form of stratification involving domination and subordination is that the linguistic and symbolic differences

between classes are often readily observed in speech and in communicative practices. The particular perspective that linguists and sociolinguists adopt towards social class will significantly shape how they research language in society.

Neo-Marxists and Neo-Weberians

Contemporary analysis of class has involved a rethink about which groupings are socially significant, and who belongs to which grouping. Neo-Marxist perspectives continue to stress social class as the most significant social cleavage. Neo-Marxists are divided into three groups of theorists: minimalists (Structuralist Marxists), maximalists, and intermediates:

1. The minimalists believe that only manual workers belong to the working class; all other members traditionally thought of as working class are more properly classified in the petite bourgeoisie. Structuralist Marxists such as Louis Althusser and Nicos Poulantzas, held this view (Althusser, 1984; Poulantzas, 1973).
2. The maximalists believe a broad band of the middle class is in fact better classified with the interests of the working class, since they are squeezed by the bourgeoisie to such an extent that their lot is similar to that of workers (a classic position can be found in Baran and Sweezy, 1966).
3. The intermediates believe that many in society fall within a contradictory class location, where their identities and allegiances are insecure and oscillate between classes. No firm social group identity can be forged under such circumstances (Olin Wright, 1985).

First introduced by Weber, the concept of closure, analyses group and class behavior in terms of the exclusion or inclusion of other social groups, and the resulting conflict, was examined by the neo-Weberian writer Frank Parkin, who categorized the workings of social closure as follows: (1) Social closure from below, a subordinate group keeps a dominant group out. (2) Dual social closure, an intermediate group keeps a dominant group and a subordinate group out. (3) Usurpationary social closure, a previously subordinate group comes to dominate and exclude a previously dominant group (Parkin, 1983).

This particular approach using social closure can also be used to link social consciousness and communicative action to class and status, which has particular relevance for the study of sociolinguistics in areas such as code switching (Myers Scotton, 1995).

Table 1 is a brief tabulation (based on Bradley, 1992: 15) of some key contemporary differences between neo-Marxist and neo-Weberian approaches.

Table 1 Comparing Neo-Marxists with the Neo-Weberians

Neo-Marxist	*Neo-Weberian*
1. Class divisions generated by relations of production	1. Class divisions generated by operation of market
2. Classes unified by exploitation	2. Classes fragmented by markets
3. Conflict between classes dominates social relationships	3. Conflict within classes as important as conflict between them
4. Middle class linked to one of major classes	4. Middle classes are autonomous groupings as significant as the propertied and working classes
5. Consciousness arises from relations of production	5. Consciousness has many different sources

(Based on Bradley, 1992: 15).

Giddens has commented that the various permutations of the meanings of social class bring neo-Weberian and neo-Marxist understandings of class very close together at times. For example, the understanding of social mobility is difficult to distinguish from 'contradictory class location,' where people appear to occupy an intermediary position and switch their allegiances and identities between classes (Giddens, 1993).

Class as Category

In stark contract to the idea of class as social formation, class as category presents a consensual, normative view of society. This idea of class has an affinity with Emile Durkheim's structuralist interpretation of the division of labor in any society, but specifically industrial society, and the structural analysis of all social institutions in relation to their social functions within society. Durkheim was interested in the basis of social order and the establishment of social norms, rather than conflict. By the 1950s, structuralism had a far-reaching impact on social thought, even influencing Marxism. Most importantly, it spawned the structural functionalism and normative sociology of Talcott Parsons in the United States (Parsons, 1964).

The approach of defining class as category, brings us somewhat closer to the original Latin meaning *classis*. By measuring income levels or classifying people into occupations, one can determine social class. This is a socioeconomic definition of class, with no reference to subjective notions of consciousness of class position and status. It is referred to as a 'scale and category' measurement of social hierarchy, which tends to permeate a bureaucratic understanding of social hierarchy. It is a form of measurement that has been used, for example, to determine actuarial

predictions of life expectancy and insurance risk, and to analyze potential markets. As a gradational measurement, it is well suited to quantitative empirical investigations of society.

The structural functionalist perspective of Talcott Parsons was the dominant postwar voice in American social theory. Parsons claimed the influence of Weber, whom he encountered as a student, and whose work he translated and published. Yet, he adopted a normative, consensual approach to social structure, and largely used the perspective of social class as an occupational role. This body of social theory emphasizes the possibility of social mobility, and has used the version of industrial democracy as developed in the United States, as its social exemplar of advanced social development. It has been influential as a framework in sociolinguistic studies, particularly in understanding of the relationship between language and social class, since variables such as income, occupation and educational level are all deployed in understanding the normative category of class. An example is William Labov's use of occupational hierarchy to assess class speech variation in his survey of New York City (Labov, 1966).

The Use of Class and Status in Sociolinguistic Research

Class, Codes and Control

Bernstein's seminal work, *Class, codes and control* was one of the first systematic attempts to investigate the cultural features of social class and its relationship to education. His concept of code, is in essence, a communication process deeply embedded in the nature of social stratification. It is not readily evident, and has therefore to be subjected to decodification and analysis in order to be rendered explicit. Drawing on the work of Marx, Weber, and Durkheim, Bernstein looked for reasons for the perpetuation of working class failure in the educational system; his research typified the turn to cultural and superstructural analysis of social inequality.

His research in 1960s Britain, consisted of a relatively homogeneous social context, with very small minority populations. As in many European societies at the time, the articulation of class interest and conflict was well reflected in the major competing political parties. Bernstein's belief was that the reproduction of working class failure in the face of postwar educational reforms could in fact be understood and rectified. He developed Durkheim's profiles of the working class and middle class family, and typified their communicative codes as 'mechanical' in the case of working class (an understood, implied process of communication with much left unspoken), and 'organic' in the case of the middle class (a more explicit negotiation of social meaning). In turn, he investigated the structure and process of communication within the schooling system, and the congruence or lack of congruence between the school and the family. He sought to establish patterns in communication and socialization that disposed the middle class to success in educational contexts.

Bernstein developed the notion of 'elaborated' and 'restricted' codes, the working class had a restricted code and the middle class an elaborated one. Code, in fact, referred to a great deal more than the surface features of morphology and syntax. Unfortunately for Bernstein, this was the feature that became synonymous with the so-called 'deficit hypothesis.'

In what was a voluminous work based on the contributions of many researchers, one Bernstein article dealt with grammatical and semantic structure and linked this, in a strong expression of the Whorfian hypothesis, to the concept of working class language being in itself cognitively deficient. It described the features of a restricted code at a syntactic and morphological level, which was thought to inhibit communication and conflict with the communicative systems in education, in contrast to the middle class elaborate and explicit code, which enhanced this process. This was in turn thought to create problems in the communicative adaptation to schooling for working class children.

This aspect of the research became enlarged and was misconstrued as the substance of Bernstein's work. In fact, as argued above, many of the features of Bernstein's analysis of the working class family drew on structuralism, and were concerned with processes of communication, which had nothing to do with surface features of language and even contradicted their importance (Atkinson, 1985). Yet, many subsequent research works repeatedly drew attention to the surface levels of working class speech, and claimed that specific means of expression were deficient and at odds with institutional forms of communication. It was also this feature of the research that made it extremely significant to linguistic and sociolinguistic discussion.

This small aspect of Bernstein's work was taken up in the educational reformism of the 1960s in the United States by a project called Operation Head Start (Bereiter and Engelmann, 1966). This project advocated the teaching of standard grammar as the solution to educational failure in the black ghettos. Drills were developed for the development of standard speech varieties; the result was to further alienate the communities from the schooling process.

The result was the celebrated but unfortunately one-dimensional critique of Bernstein developed by

William Labov in support of the logic of nonstandard English of African-Americans, the key target of educational reform at the time. The implied acceptance of the strong version of the Whorfian hypothesis in Bernstein's work was the basis for the critique. Labov demonstrated very adequately how surface features and sociolect had nothing to do with rational thought and established, in contrast, the difference hypothesis (Labov, 1966). This much-remembered debate, in many ways, was built on straw characterizations of each side of the argument.

Bernstein did not anticipate that his work would be used in the context of a minority status group along with a prejudiced perception of the group's speech patterns. He did not expect the degree of misconstrued interpretations of his work in the United Kingdom. Any validity on the sociological side of Bernstein's research was muted in the face of the barrage of criticism that was directed against what was perceived to be a restatement of class prejudice in his work.

There were in essence many more concerns in Bernstein's research, not least of which was the acquisition of literacy, the graphic shibboleth of all educational systems. The linguist Halliday defended Bernstein's work and qualified his understanding of it, on the basis that it was concerned with questions of literacy, and creative work in educational practice. As Bernstein himself pointed out, "We are told and socialized into what to reject, but rarely told how to create (Bernstein, 1977: 167)." Much was produced in the concern for language across the curriculum, and the methods of teaching reading and writing that emerged from this period of critical debate about language teaching and the development of literacy in the United Kingdom at the time (Hasan, 1996: 34; Halliday, 1978). The debate over restricted and elaborated codes and its tenor probably lost more ground for sociolinguistic enquiry than it gained.

Bernstein continued to look at notions of horizontal and vertical knowledge and issues that are of central concern to sociology in more recent times. Bernstein's death in 2000 led to a great deal of revisiting of his work (Moore and Muller, 2002: 627).

Variation Studies and Class as Category

A number of large-scale quantitative studies on language variation were conducted in the 1960s and 1970s, by researchers such as Trudgill in the United Kingdom and Labov in the United States (Trudgill, 1974; Labov, 1966). These studies were symptomatic of the nature of quantitative social enquiry at the time, but their important common feature was that they focused on socioeconomic and stylistic stratification of linguistic variables over large populations. This approach adopted a consensual view of language and social class; that is, class as category, as outlined above. For a period, these approaches sought to define linguistic and sociolinguistic research endeavor as having scientific validity.

Table 2 Labov's class categories

Category	*Description*
Upper class	First rate professional, manager, official, or proprietor of a large business
Upper middle class	Career man in professions, managerial, official, or large business positions
Lower middle class	Semiprofessional, petty businessmen, white collar, foreman, and craftsman
Working class operatives	Blue collar workers dependent on labour market
Lower class	Laborers with insecure job status

(In Eckert, 2000: 26).

Labov's work is interesting in that it applies a very clearly developed category approach to class. The categories he used in his survey of New York City in 1966 are shown in Table 2 (from Eckert, 2000: 26).

This research is very much part of the investigation of cultural phenomena and their relationship to class, which has been typical of the postindustrial research endeavor, particularly in advanced industrial societies. The consensual nature of this form of social investigation is criticized for failing to portray the dynamic nature of social change and innovation necessary for social explanation. What Labov produced with this research was a series of functionally explained categories, where occupation was seen as the very basis of class, and the agent of language change. For him, it proved the plasticity of the vernacular and the endurance of the standard variety.

His identification of the linguistic insecurity in the lower middle class, and the desire for hypercorrection on both a class basis and a gender basis, is interesting for its depiction of class semiotic and its interface with a status group such as gender. Little is made of the social groupings and networks in the construction of the standard and vernacular that Labov portrays on his linguistic scale: the interpretation of different styles and relation to social class is limited.

Labov's former student, Penelope Eckert, has completed an interesting reinterpretation, using a Bourdieu-like analysis of the networks that sustain standard and vernacular forms. She shows the significance of past and present variation studies for current social description and understanding of the nature of social class and status (Eckert, 2000: 16). Her work represents an ongoing debate with Labov, which makes the latter's work as pertinent today as Bernstein's.

Bourdieu's Cultural Capital, Linguistic and Symbolic Markets

Pierre Bourdieu is perhaps the strongest voice in sociological writings, other than Bernstein, to have rearticulated the question of culture and its meaning in the stratification of society. He has developed the concepts of 'cultural capital,' 'fields,' and 'habitus.' Cultural capital is the value placed on an aspect of culture; a field is an area of endeavor, such as education; and a habitus is 'embodied social structures that serve as principles organizing practice.' His work has permeated the field of sociolinguistics since his first essays on the linguistic market on the value of the symbolic system to the accumulation of cultural capital. His work has been highly influential.

Class codes, unlike Bernstein's elaborated and restricted, are simply described by Bourdieu and his associate Passeron in terms of 'bourgeois,' and 'common' parlance. A Latinate vocabulary and a striving for novel expressions mark bourgeois parlance. Common parlance is characterized by situational reliance, nonlearned vocabulary, and reliance upon shared figures of speech (Bourdieu and Passeron, 1977: 116). The bourgeois code is fostered in the educational system, and where the dominant language is also the official language. The privileged, through their command of a bourgeois code, are better able to cope with the demands of the education system. Those students who possess common parlance cannot develop an understanding of what might be expected of them in such a field. Bourdieu, unlike Bernstein, did not express any hope for educational reform through remediation, as he treated the schooling system as one that systematically served the interests of class-divided societies.

For Bourdieu, the concept of linguistic capital is but one dimension of the concept of cultural capital. Language use is valued in different domains. The state, Bourdieu argues, unifies the linguistic market. He asserts that the school-based standard language underpins the requirements of a literate class, in which text falsely corresponds with truth and social domination is represented falsely as mental development.

As influential as Bourdieu's work has been, it has also attracted criticism. Collins argues that the determinist nature of class in his work is not able to deal with both structure and agency/practice in understanding the subjective conditions of dominated groups (Collins, 1993: 121–123). It is this balance between structure and agency in understanding social class that Giddens has termed 'structuration' (Giddens, 1979). Eckert has also drawn on this more complex concept of social class and its social determinants in her work (Eckert, 2000: 44).

Sociolinguistics is concerned with sociological explanations of the semiotic system. According to Eckert, a social theory of language cannot view *langue* as a given, but must be about the process of being conventional. What the creolist Le Page claims is needed is to understand how languages are 'named, formalized, standardized and totemized by society' (Le Page, 1997: 32). The ideas of ideal speaker and listener, and the dichotomy of competence and performance, are abstractions that are meaningful only in the context of showing us the nature of domination and subordination in understanding language and society. In this regard, Bourdieu is not alone in going to the root of questioning the very concept of 'a language' in order to provide it with an adequate sociological explanation (Bourdieu, 1992: 43–65).

Social Network and Social Class

Milroy and Milroy argue that the concept of being 'local,' or district-based is strongest amongst working class communities. They build on the arguments of Thomas Hojrup, who found that working class communities are more fragmented than others, and developed a concept known as a 'life mode' analysis, to construct a model that examines cultural aspects of social existence. In their research in Belfast, Milroy and Milroy traced the existence of close-knit networks that served as the basis for vitality of the vernacular forms of working class language. Williams has criticized this perspective as being a rejection of sociological analysis, on the grounds that network theory is incompatible with social class. Le Page defends the Milroy network research, by claiming that their network theory is both compatible with social class analysis and a useful tool to explore working class solidarity and linguistic identity (Milroy and Milroy, 1997: 61; Le Page, 1997; Hojrup, 1983). This technique for exploring language change and understanding the manifestations of class and status has been followed in a number of studies (Le Page, 1997; Williams, 1992).

Sociolinguists have sometimes naively deployed the concepts of class and status on the supposition that 'language mirrors society.' The relationship is rather more complex. Class and status are not fixed notions in sociology and have been interpreted very differently, as has been seen. Sociology and social theory are now moving beyond the characterization of the societies we live in as 'postindustrial,' and now look to the notion of the transition in capitalism to 'the iron cage of the information age,' and the rise of the network society and the rapidly changing nature of local social class and status groups globally (Castells, 1996). The

implications for the understanding of language in society are enormous, the way forward is to maintain close but critical links between the ideas of social class, social status, and sociolinguistic theory.

Social Construction and Language

Nonanalytic Approaches

According to Georg Wilhelm Friedrich Hegel the topic of "language and social construction" encompasses everything there is. I note this all embracing approach to contrast it with how these topics are discussed today. This article will focus on one view concerning the relation between language and social construction, namely John Searle's approach, which at the same time will serve to introduce into the fundamental problems. It will be necessary, however, to show first how this specific way of situating and addressing the problem evolved.

Subsequent to Hegel one can distinguish roughly four lines of thought: (1) the social theorists, ranging from Karl Marx through Emile Durkheim to Max Weber and modern sociology, (2) hermeneutical philosophers, from Wilhelm Dilthey through Edmund Husserl and Maurice Merelau-Ponty to modern post-structuralism, (3) the analytic philosophers starting with Gottlob Frege, Bertrand Russell, and Ludwig Wittgenstein up to modern analytical philosophy. Specific problems of social constructions are (4) also discussed in various disciplines such as jurisprudence, economics, and political science, sometimes accompanied by philosophical inclinations. However, none of these traditions is totally exclusive of the others. Even though the topic 'language and social construction' features in all such discussions, this article will only consider the analytical tradition.

Analytic Approaches

Early Analytic Approaches and Social Construction

The second generation of Analytic philosophers were in the beginning firmly rooted in either logical positivism or ordinary language philosophy. Their original objectives were to reveal the logical structure of language or to solve philosophical puzzles by analyzing the ordinary usage of words. Both schools of thought shared an empiricist and scientific attitude. For this early reason, analytical philosophers showed little interest in social and political reality or history. A few philosophers within the analytic tradition did pay attention to institutions, however, most notably Peter Winch (1958) and David Lewis (1969). Winch argued on the basis of Wittgenstein's *Philosophical Investigations* that explaining human action requires an understanding of the forms of life established in the society wherein the action is carried out; hence objective, culture independent explanations like those found in the natural sciences are unavailable in the social sciences. David Lewis, on the other hand, gave a game theoretic account of conventions as a solution to recurrent coordination problems. While Winch tried to justify the traditional distinction between the approaches in the natural sciences and the social sciences, Lewis examined ways of reconstructing classical arguments of social philosophy using modern means. Recently John Searle has developed an ontology of social facts and, in particular, of social institutions based on his speech act theory and philosophy of mind (Searle, 1995). This development marks the beginning of a renewed interest in social facts within analytic philosophy.

John Searle's Approach

Social Construction John Searle's first major work was on speech acts, where he first pointed out the distinction between brute facts and institutional facts, and highlighted the particular role of constitutive rules in the creation of institutions (Searle, 1969: 50–53). He subsequently based the foundations of speech act theory on his philosophy of mind (Searle, 1983). Searle then returned to institutional facts to elaborate his point more systematically. He uses three concepts as building blocks for his theory: the assignment of functions, collective intentionality, and constitutive rules of the form "X counts as Y in context C" (Searle, 1995: 13). Taking the "scientific worldview" for granted, Searle starts with the puzzle of how it is possible that there are objective social facts, such as "George Washington was the first president of the U.S.," within a world composed entirely of minute physical particles. Searle's basic proposal is that we assign functions both to naturally occurring objects (e.g., using a stone as a paperweight) and to those created for the purpose of performing an assigned function (e.g., using a hammer) (Searle, 1995: 13–23). Searle argues that such functions are never discovered in nature, like the natural properties of weight, color, etc., and cannot be completely reduced to causal explanations. Instead they are always imposed on things by intentional actors. Functions thus are always observer relative. This distinction is crucial because it allows us to mark the difference between features of reality that are observer independent (e.g., gravity, force) and usually described by the natural sciences and those that are observer dependent and usually dealt with by the social sciences. The latter features are always partly constituted by an ontologically subjective set of attributes (intentions);

nevertheless they can in the case of institutions still be epistemically objective.

Searle also uses the imposition of functions to explain the meaning of words and signs. According to Searle, meaning arises whenever we assign functions to things as to symbolize, represent, or stand for something. Hence a red traffic light signals 'Stop!' because we have assigned this function to red lights in boxes at the roadside. Searle's theory of meaning is taken for granted. The relevant point here concerns only the relation between the natural world and the social world of animals and humans. While Searle attempts to adhere to the program of realism he nevertheless makes frequent use of terms like intentions, functions, etc. According to Searle they are compatible with the scientific worldview of realism since he claims intentionality, the prerequisite for the imposition of functions, is a "higher level feature of the brain."

Searle uses the same scheme of explanation to introduce the second building block of his theory, collective intentionality (Searle, 1995: 23–29). He sees collective intentionality or 'we-intentionality' as a "biologically primitive phenomenon" that cannot be reduced or eliminated in favor of something else. Searle, in particular, stipulates that it cannot be reduced to "individual intentions plus something else." Whenever people engage in cooperative social action, Searle argues, there has to be "collective intentionality at a higher level." This concept holds true for a violinist playing in an orchestra and even for certain hostile activities like litigants in a legal proceeding or two faculty members trading insults at a cocktail party. Searle holds that all these are social facts that involve the 'we intentions' of the parties.

Finally, constitutive rules of the form "X counts as Y in the context C" are employed to explain the difference between brute facts and institutional facts (Searle, 1995: 27–29). According to Searle, brute facts, such as that gold is a chemical element, exist independently of social institutions. Only the sentence "gold is an element" depends on the institutions of language and science. Institutional facts, on the other hand, such as the scoring rules of football, depend for their very existence on conventional agreements and on the acceptance of such conventions by the group taking part in the game; they are not pregiven. To explain institutional facts Searle further distinguishes between regulative and constitutive rules. Regulative rules govern preexisting activities, like driving on the right side of the road. The activity of driving (on either side of the road) existed before it was made obligatory to drive on the right. Constitutive rules, on the other hand, create the very possibility of an activity. Without the rules of football there would be no such game, and kicking a ball between two posts would not count as scoring. Searle concedes that the distinction between regulative rules and constitutive rules cannot always be strictly drawn as many constitutive rules rest on preexisting activities that might be governed by regulative rules. In any case, it is a distinction within the realm of social facts. All institutions are then built by using a system of constitutive rules of the form "X counts as Y in the context C" (Searle, 1995: 43–51). Thus, shooting a ball between posts (X) counts as scoring (Y) in a football game (C). The X term stands for some object or activity, to which (via collective intentionality) a certain status function has been assigned.

The most obvious example of social facts, explainable along the lines of Searle's analysis, is an institution such as money. Status functions are assigned on certain pieces of paper. Such statements require an involvement of collective intentionality; hence the paper functions as money only as long as we consider it to be money. It is moreover dependent on a specific context. The formula is useful for explaining standard cases, though it allows as well for the reflection of unusual cases. A standard case might be: 'Bills issued by the Bureau of Engraving and Printing (X) count as money (Y) in the United States (C).' The existence of a 'cigarette currency' in post-war Germany might be an unusual case: 'American cigarettes (X) counted as money (Y) in post-war Germany (C).' With these basic distinctions at hand it is possible to give a 'hierarchical taxonomy of (certain types of) facts' starting from brute facts and going up to institutional facts (Searle, 1995: 37–43).

The Role of Language Searle's approach makes obvious why social construction is a linguistic activity. Collective intentionality alone does not require language or any symbolic means as it may be presupposed that even a pack of wolves hunting together are engaged in a collective enterprise. Indeed, Searle assumes that animals have intentionality. The difference comes only with the imposition of the status functions.

In moving from the X to the Y term the matter of the X term does not change, it only acquires a new meaning. It is used to symbolize something that exists only by virtue of a collective agreement. This theory requires some elucidation. Symbols are often (but not always) used to refer to objects that exist independently of the symbols and even independently of language. The symbol 'cat' refers to cats; and cats exist independently of any symbol referring to them. The imposition of status functions on something, on the other hand, creates a new category of objects or actions that have not existed prior to symbolization

and collective agreement. The difference is made obvious by comparing social behavior of animals and humans. Certain animals might live in lifelong pair-bonding but they will nevertheless not be married, as they do not have the institution of marriage. That humans are married cannot be read off their behavior either but has to be declared in a certain situation. The declaration of marriage is an indispensable linguistic activity as only by virtue of the symbolic act are certain rights and duties granted. Institutions hence create reasons for action that depend on forms of symbolization. The initial act is usually thereafter represented by some symbolic means, Searle calls them status indicators, as e.g., wedding rings or a marriage certificate.

A further sign evincing their linguistic nature is that status functions are intensional and cannot be replaced *salva veritate* by coextensive expressions. Hence, even if it is true that 'marriage ruins the sex life,' it does not follow that 'exchanging rings counts as "ruining sex life" in the context of a church ceremony.'

It should be kept in mind that the formula is meant not only to explain the creation of institutions out of brute facts but as a general explanation. Therefore, institutional facts are permissible at the place of the X term so that social facts can be reiterated. Indeed, Searle notes that language itself is an institutional fact that can be analyzed using the formula.

However, this feature reveals a fundamental problem. One of Searle's main objectives is to show how institutional facts emerge out of natural facts through language. If, however, language is an institutional fact in itself, the formula merely highlights a structure within the realm of institutional facts but cannot ultimately explain the emergence of institutional facts. Searle addresses the problem merely by stating that language is a special kind of institutional fact, namely one that is "designed to be a self-identifying category of institutional fact" (Searle, 1995: 73).

Critical Assessment

Searle labels his approach "philosophy of society," analogous to classic fields like philosophy of language or philosophy of mind. Three kinds of criticisms in reaction to Searle's proposal have emerged. Those who agree in principle with Searle's line of thought dispute specifically the concepts of collective action and collective intentionality (Gilbert, 1989; Bratman, 1999; Tuomela, 2002). There are, on the other hand, two kinds of criticisms questioning Searle's approach in principle. Some philosophers hold that Searle misses the fundamental role ordinary language plays in conceiving reality at all, since Searle presupposes implicitly that the world as described by the natural sciences can be attained independently and prior to the everyday social world, hence independently of ordinary language. Social scientists, on the other hand, criticize Searle for failing to account for social facts properly, since social facts pertain to the explanation of actions, a feature Searle omits in his philosophy of society. The different kinds of criticism do not exactly correspond with the lines of thought mentioned in the beginning; however they show that the philosophical discussion is still divided over fundamental questions.

Social Psychology and Language

J J Bradac and S A Reid, University of California, Santa Barbara, CA, USA

Introduction

Humans are symbol-using creatures. Aristotle claimed that humans are political animals (*anthropos politicon zoon*), but arguably a stronger claim is that humans alone are **linguistic** animals, the recent attempts to teach special symbols to chimpanzees and dolphins notwithstanding. The argument that humans are essentially and uniquely symbol users has been made forcefully by various scholars. In light of the special status of language, it is not surprising that linguistics, the science of language, emerged well over 2000 years ago and is still flourishing in the 21st century. However, humans are also psychological animals (although not uniquely so), hence the rise of psycholinguistics. Additionally, humans are social animals (again not uniquely), hence sociolinguistics. One of the most recent human science specialties to emerge acknowledges all of these facts: the social psychology of language (SPL).

Definition and Key Concepts

Language has both social and psychological antecedents and consequences. The social psychology of language investigates these causes and effects scientifically. Thus, the social psychology of language can be described as the scientific study of language in its social and psychological contexts. Three major concepts underlie this definition: society, mind, and language. 'Society' refers to the fact that humans form relationships with other humans and that they live in and identify with groups. Relationships exist between and among individuals within and between social groups. Both interpersonal relationships and larger social groupings are represented cognitively. People think about and evaluate these social entanglements, or in other words, people have attitudes toward them. Attitudes are important components of 'mind,' comprising beliefs and corresponding evaluations: "Politicians talk and don't act, and I dislike this." Attitudes are linked to stereotypes, which are often defined as beliefs about social groups: "Asians are intelligent." As the previous example shows, stereotypical beliefs often have an evaluative aspect. A very large body of research demonstrates that people also have attitudes toward and stereotypes about languages and dialects, and within these, toward molecular features of speech, such as hedges ("it's *sort of* good"), hesitations ("it was ... *uh* ... nice"), repetitions of words (lexical diversity or vocabulary richness), language intensity ('hate' versus 'dislike'), and many other forms.

Bradac (1999) has suggested that 'language' can be construed as three related but distinct objects of research and theorizing. Language$_1$ is examined by conversation analysts and discourse analysts. It is a flexible system that speakers use to achieve interpersonal goals and to perform tasks demanding communication for their accomplishment. Researchers viewing language in this way attend to fine details of lexical arrangement as these are used to communicate nuanced meanings in specific situations. Meanings are locally determined. Researchers may examine the different uses of 'you know' or the different meanings of 'hello' versus 'hi.' Various communicative routines and interaction rituals are also investigated. The grammaticality of utterances is interesting only to the extent that it affects idiosyncratic meanings in context. Importantly, researchers studying language$_1$ rarely invoke the notion of mind when explaining the workings of a segment of conversation.

On the other hand, individuals studying language$_2$ may well show recourse to mentalistic explanations, as in contemporary cognitive linguistics or Chomsky's (1968) classic *Language and mind*. Language$_2$ is a possibly innate, uniquely human, hierarchical, rule-governed communication system, typically studied by linguists. The idea of hierarchy suggests that language$_2$ is a structured entity with interrelated levels spanning phonology, morphology, and syntax. One of the historically important tasks of linguists is the construction of grammars of natural languages, and perhaps eventually (and chimerically), a Universal Grammar. In the latter respect, researchers investigating language$_2$ are very different from those studying language$_1$. However, they do share an interest in the creative properties of language (e.g., being able to say **anything**), which typically entails a philosophical rejection of determinism and logical positivism.

Language$_3$, on the other hand, is studied by researchers who are logical positivists, at least in practice. It is a heterogeneous set of verbal variables that are often controlled by psychological processes. Language$_3$ is a collection of verbal features that are often influenced or even determined by environmental, physical, or psychological variables that are not under the conscious control of speakers. The collection has no internal structure; instead, each collected item reflects a theory or concept of interest to a diverse

group of social psychologists and communication researchers. For example, utterances necessarily exhibit some level of lexical diversity (redundancy) that varies across speakers and occasions (Bradac *et al.*, 1979); diversity level is affected by anxiety and neurological pathology (aphasia). Utterances may also exhibit varying levels of language intensity; relatively intense language ('I despise cigarettes') signals a speaker's departure from attitudinal neutrality (Bowers, 1963). To give a final example, speakers vary in linguistic power; some persons use many hedges ('sort of good') and tag questions ('good, **wasn't it**?'), whereas others do not (Ng and Bradac, 1993).

Language$_3$ carries a special meaning for language and social psychology (LSP) researchers, who vary in the extent to which they are familiar with or even work with the meanings of language familiar to conversation analysts or linguists. It is certainly the case that LSP researchers who study the effects of dialect or accent on impression formation understand a part of the meaning of 'language' for linguists (Giles and Powesland, 1975), but these researchers exploit this part for unique purposes. On the other hand, language$_3$ is probably unfamiliar to many linguists and conversation analysts, and it may seem to be a strange conception if they happen to encounter it. The three meanings of 'language' suggest a fairly high degree of separation that could lend itself to exaggeration; the meanings actually have areas of overlap.

More pertinently, dissimilar metaphors have been dominant in competing movements in psychology. British and American introspective psychology of the late 19th and early 20th centuries inherited the Cartesian mind-body dualism: both mind and body are real, but they are independent entities, which allowed self-conscious investigations of the mind's contents. Introspectionism was replaced by John B. Watson's behaviorism (in America) which exploited a radically different metaphor: humans are machines that are energized by environmental forces; mind does not exist, but the body's observable behavior does. The ultimate expression of this kind of metaphor may well be Skinner's *Verbal Behavior* (1957), in which humans are viewed as talking machines, emitting 'tacts,' 'mands,' and other classes of utterance; language is a type of behavior, essentially the same as any other behavior, like scratching an itch. This view of language allowed and stimulated a large stream of studies on verbal conditioning (Brown, 1958: 182–186). For Chomsky and post-Chomskian social cognitivists in social psychology and communication, humans are essentially disembodied minds, making plans (Berger, 1997) and processing information (Fiske and Neuberg, 1990), a reversion to a version of the Cartesian metaphor (*cogito ergo sum*).

In LSP, a guiding metaphor was articulated by Giles: "Humans are not sociolinguistic automatons" (Giles, 1979). This view was offered in reaction to an implicit metaphor underlying the work of Labov, Hymes, and others who can be construed as having argued that phonological, lexical, and other linguistic features vary as a function of group membership and situational constraints; these memberships and external constraints **force** particular forms of language (Giles, 1979). This view certainly is not entirely incorrect, but it does not attend to the important role of individual psychological states, intentions, and motivations that can affect language performance. Individuals may converge to or diverge from the language of an interlocutor depending on their needs for social approval or group distinctiveness. Speakers can intend to parody a foreign accent in order to produce laughter in hearers. Although communication contexts may tend to coerce certain forms of language behavior in passive adherers to norms, language can be used **actively** by speakers to shape or even establish the context (Giles and Hewstone, 1982). Although hearers may tend to be affected predictably by messages exhibiting various language styles, individual response differences will occur as a result of different goal orientations, attentional sets, and personality variables (Cargile and Bradac, 2001).

Another fundamental assumption of LSP researchers, which need not be developed at length, is that signs and symbols, which are simultaneously social, mental, and linguistic phenomena, are the basic elements in the human universe. This is in contrast to, say, neo-behaviorist psychologists for whom 'habit' is the irreducible particle. Thus, Ng and Bradac (1993) discuss 'signs of power,' a term that refers to language features that provide information to hearers about a speaker's social status, intellectual competence, and authoritativeness. Other verbal signs provide information about a speaker's apparent sociability, trustworthiness, and attractiveness (Giles and Ryan, 1982). Verbal signs are diagnostic for hearers. Typically, they exist outside of a speaker's awareness and control, as in the case of a dialect or level of vocabulary redundancy. Signs have a one-to-one relationship to their referent: dialect$_w$ –> Welsh group membership. By contrast, symbols have multiple referents; they are ambiguous and flexible. Speakers use them consciously and strategically to accomplish any conceivable purpose: writing a poem, seducing a stranger, flattering a boss, constructing a theory, and a million other things. Signs are on the surface; symbols probe the depths.

Relationships with Allied Areas

One could use the term 'socio-psycholinguistics' to label LSP, but that would be awkward. However, the term suggests what are probably the two most closely allied areas of research, psycholinguistics and sociolinguistics. Psycholinguistics emerged in the early 1960s as a result of a new interest in the mental processes and structures underlying humans' use of language, to a large extent an effect of Chomsky's theorizing. An interest in 'mental processes and structures' could not have existed for traditional descriptive linguists working under the sway of behaviorism. From its inception, psycholinguistics has focused closely on issues of child language acquisition, initially child grammar (Brown, 1970), and more recently, the development of pragmatic competence (Pedlow, 2001). Other classic psycholinguistic topics include the measurement of connotative meaning, semantic memory, relationships between language and thought, psychological aspects of second language learning, and the organization of the 'mental lexicon' (Aitchison, 1994). Important psycholinguistic researchers at the field's inception included Brown (1970), McNeill (1966), Miller (1963), and Osgood (Osgood *et al.*, 1975). Although psycholinguistics is the offspring of both linguistics and psychology, over the years it has relied heavily on the quantitative, experimental methods of psychology rather than the descriptive, intuitive methods of linguistics. It is probably accurate to say that the typical psycholinguistic experiment pays scant attention to social phenomena, although not surprisingly, in some cases the border between psycholinguistics and LSP is fuzzy.

The roots of sociolinguistics go back to studies of dialects in the early 20th century, but the explicit study of relationships between social stratification and language performance emerged in the 1960s (at the same time as psycholinguistics). In this case, social issues in the larger society, such as racial and ethnic relations, provided an important impetus to sociolinguistic research, a pattern that differs from that of psycholinguistics, where the early research problems emerged almost entirely from **within** the community of interested scientists, more in line with the tendencies of Kuhn's 'normal science' (1970). Important sociolinguistic researchers at this time included Labov (1966), Trudgill (1974), and Shuy (1969). A good deal of the research attempted to describe phonological and syntactic differences between groups that were differentiated along the dimensions of race, social class, and geographical region, and this kind of research is still apparent (Ito and Preston, 1998). Recent sociolinguistic research has broadened its focus to include the study of social networks and language performance (Milroy, 1980), of social context and language registers (Caporael, 1981), and of lay beliefs about dialects and dialect boundaries (Preston, 1986). This research overlaps with LSP.

So, to exaggerate a bit, sociolinguistics attends to social aspects of language, while largely ignoring the mental underpinnings of linguistic phenomena; psycholinguistics examines these underpinnings while largely ignoring variables such as social group membership; and prototypical LSP research examines the social and psychological bases of language, as in the case of language-attitudes studies that focus on group membership, group language, and hearers' psychological reactions to this language.

Several styles of theorizing are apparent in LSP, although some are more typical than others. There are concatenated theories (Reynolds, 1971), which exhibit an open, web-like (as opposed to propositional) structure and are often densely verbal, communicated at length in book form. This type of theory may be highly suggestive and stimulate large thoughts, but it may also be difficult to test empirically. An example may be Babrow's problematic integration theory (1992). Probably more typical are causal theories that suggest testable hypotheses depicting a relationship between an antecedent variable and a consequence. Giles's communication accommodation theory is a prototypical example (Shepard *et al.*, 2001). Causal process theories depict a chain of causes that constitute the mechanism that explains a bounded process; they may be modeled as an input-mediator-output structure (Pavitt, 2000). Axiomatic theories are highly formalized explanatory instruments containing basic propositions (axioms) that are combined via some logical rule to form higher-order propositions (theorems). Causal process theories may assume an axiomatic form (Berger and Calabrese, 1975; Bradac *et al.*, 1980). Finally, mathematical theories, as the term indicates, contain interrelated propositions expressed in mathematical form. This constitutes an 'empty set' in LSP currently. Mathematical theories and concatenated theories are maximally distinct formally.

Predominant Theories of LSP

The Social Identity Approach

The social identity approach stands as a meta-theoretical perspective that frames a set of influential theories in LSP. Starting with ideas (Tajfel, 1974) that were formalized as social identity theory (Tajfel and Turner, 1979), the uniting assumption is an interactive meta-theory. Social psychological processes articulate with social perceivers' understanding of their

social environment to predict language use, attitudes, beliefs, and behavior. This perspective incorporates but is not limited to social identity theory, ethnolinguistic identity theory (Giles *et al.*, 1977; Giles and Johnson, 1981, 1987), communication accommodation theory (Giles, 1973; Shepard *et al.*, 2001), self-categorization theory (Turner *et al.*, 1987), and the social identity model of depersonalization effects (Reicher *et al.*, 1995). Among many other phenomena, these theories have been applied either directly or in combination to understanding second language learning, code-switching, semilingualism, diglossia, patterns of language attitudes and language shifts, gender and language use, power in language, leadership, and computer-mediated communication.

The impetus for the application and development of social identity ideas to language phenomena came in two forms. First, Giles (1973) interpreted Labov's (1966) data on shifts in post vocalic /r/ in New York City. Giles suggested that linguistic shifts between contexts – interpreted by Labov as reflective of situational formality – could also be interpreted with respect to the motivations of respondents in accommodating the perceived language style of their (experimenter) interlocutors. In other words, situational cues were mediated through respondents' motives to linguistically approach (accommodate) or distance (diverge) from their interlocutors. Empirical confirmation led to the development of speech accommodation – and later, communication accommodation theory (Shepard *et al.*, 2001). People accommodate linguistically and/or non-verbally in myriad ways: under-accommodation, over-accommodation (e.g., patronizing speech), mutual accommodation, and unilateral accommodation. It is assumed that accommodation towards an interlocutor is motivated by a desire to show liking, whereas divergence away from an interlocutor satisfies a motive for positive intergroup distinctiveness.

Critically, the power of communication accommodation theory was not fully realized until a second development of social identity theory was made: ethnolinguistic identity theory (Giles *et al.*, 1977; Giles and Johnson, 1981, 1987). Ethnolinguistic identity theory was designed to explain macro-social processes – broadly speaking, language survival and death. Ethnolinguistic identity theory accomplishes this by elaborating the logic of social identity theory. By understanding a social perceiver's identification level, the perceived stability and legitimacy of the status between relevant groups, the possibility of shifting between groups, and the subjective vitality of those groups, it is possible to delineate three (in practice, even more) intergroup orientations. These orientations – social mobility, social creativity, and social conflict – in turn predict the communicative shifts discussed in communication accommodation theory.

A mainstay of work in LSP has been language attitudes, an area where ethnolinguistic identity theory has been particularly powerful. Lambert *et al.* (1960) devised the matched guise technique (MGT) for measuring language attitudes. The impetus for developing the MGT was to investigate stereotypes of speakers uncontaminated by social desirability motivations in subjects. To do this, subjects are told that they will be asked to make personality inferences of different speakers from brief recordings, much as we quickly develop ideas about the personality of someone on the radio from listening to them briefly. Unknown to subjects, however, it is the same bilingual speaker speaking in a different guises – French-Canadian versus Anglo-Canadian in the original study. The advantage of the MGT is that it makes it possible to control for individual differences in speaking style (i.e., prosodic and paralinguistic features) while varying only the language or accent of the speaker. Any differences in beliefs about the 'personality' of the speaker are therefore attributable to group differences. Research shows that two dimensions of social evaluation are most common: status (e.g., intelligence, competence, wealth) and solidarity (e.g., integrity, benevolence, social attraction).

Work on language attitudes followed a descriptive empirical path unguided by theoretical concerns for some time. Different patterns of language attitudes for different groups – even different patterns for the same group over time – were found (see Giles and Coupland, 1991). However, Giles and his colleagues showed that much of the variation could be understood using ethnolinguistic identity theory. Lambert *et al.*'s original (1960) study demonstrated that French-Canadian and Anglo-Canadians alike downgraded the former on dimensions of status and solidarity. This suggested social mobility/group assimilation beliefs. This pattern occurs when the dominant group has overwhelming vitality; subordinate and dominant members identify with the dominant group. Both perceive that the boundaries between groups are permeable and that the vitality difference is legitimate and stable. Social mobility is then realized as identification with the dominant group. Other findings could be interpreted as evidence of social creativity. For example, Cheyne (1970) studied the language attitudes of Scots and English and found that while the former was rated higher on solidarity variables, the latter was rated higher on status variables. This pattern occurs when identification with the group is high, group boundary permeability is low, but both groups wish to avoid direct competition. In

such cases, positive identity for the ingroup is achieved by finding a dimension of comparison that enables positive distinctiveness. Finally, Lambert *et al.* (1965) studied the language attitudes of Arabs and Israelis and found mutual downgrading on status and solidarity dimensions – a pattern consistent with social competition social beliefs. This pattern occurs when group members believe that social competition will achieve dominant status for the ingroup.

The Linguistic Category Model

In their linguistic category model (LCM), Semin and Fiedler (1988) proposed a linguistic counterpart to attributional biases in person perception such as the fundamental attribution error (Ross, 1977) – the phenomena where people are more likely to make internal attributions for their successes (e.g., 'I'm a smart person') than for their failures (e.g., 'that test was difficult'), whereas the reverse is true when people make attributions for other people. Semin and Fiedler proposed that such biases are reflected in – and in turn affected by – word choice. According to the LCM, people and their actions can be described by four linguistic categories that vary along a dimension of concreteness-abstractness. Descriptive action verbs (e.g., *punch, kiss, run*) are the most concrete, referring directly to the behavior concerned. Such descriptions tell us little about the attributes of the person who engaged in the act – any number of attributions might be applied. Interpretive action verbs (e.g., *hurt, court, training*) are more abstract and tell us more about the meaning of the given behavior, but still such descriptions tell us little about the actors' reasons for engaging in the behavior. State verbs (e.g., *be angry, be aroused, love sport*) refer to the internal emotional and motivational states of the action and therefore constitute a person attribution, albeit one that can be highly unstable. Finally, the same person or actions can be described by adjectives (e.g., *aggressive, nymphomaniac, athletic*). Such descriptions are the most abstract and imply most about the dispositions of the actor.

The most sustained research employing the LCM has been on the linguistic intergroup bias (LIB) (Maass *et al.*, 1989). The LIB occurs in circumstances where people who identify strongly with a group are given the opportunity to describe the actions of members of the ingroup or a relevant outgroup. Given these background conditions, people describe positive ingroup and negative outgroup actions using more abstract language than they use when describing negative ingroup and positive outgroup actions. Much research has focused on testing explanations for the LIB. Maass *et al.* (1996) tested an identity threat explanation that implicated the motive for social identity enhancement. Maass *et al.*'s reasoning was that the LIB should only result when one's ingroup is threatened in some way by an outgroup member (e.g., being criticized), but not when relations between groups are construed as cooperative. Maass *et al.* found an accentuated LIB when under ingroup threat and an attenuated LIB under the no-threat condition. While the LIB is sensitive to self-enhancement motives, there is still residual variance to explain. Maass *et al.* (1995) tested a differential expectancy explanation. Perhaps it is the case that people simply describe behaviors that are in accordance with stereotypical expectations, regardless of valence? Maass *et al.* (1995) demonstrated that this is indeed the case – regardless of whether ingroup and outgroup stereotypes were negative or positive, people described behavior consistent with those stereotypes in more abstract language. While progress has been made in understanding the causes of the LIB, research continues to reveal new moderating variables. For example, Douglas and Sutton (2003) showed that the LIB can vary with strategic intent – findings that are not readily explainable using identity protection or expectancy explanations.

An additional implication of the LIB is that it may partly explain why stereotypes are notoriously difficult to change (Maass, 1999). Stereotypes are most negative during intergroup competition, and such stereotypes are linked with intergroup discrimination. It is also under these circumstances that the LIB is found. The LIB communicates stereotypes and by so doing may reinforce those stereotypes.

Uncertainty Reduction Theories

Uncertainty reduction theories have been very common in the field of communication. Berger and Calabrese (1975) began with a concern with the role of uncertainty reduction in initial (interpersonal) encounters, but this was expanded to ongoing interactions by Berger and Bradac (1982). The starting assumption was that coping with uncertainty is a central issue in the production and reception of any communication. People must deal with their uncertainties to be able to communicate effectively. Following the Yerkes-Dodson law, very high uncertainty is stifling and decreases communication (imagine trying to communicate a complex idea to a foreigner), moderate uncertainty is optimal for communication, and very low uncertainty is unlikely to carry the motivational force to lead one to communicate at all. Uncertainty can be about ourselves or about our communication partners; it can be cognitive (i.e., uncertainty about values, attitudes, beliefs, and feelings) or behavioral, explanatory or predictive. Uncertainty is reduced by engaging in communicative

strategies. Strategies can be passive (e.g., watching people talk to others), active (e.g., asking others about the individual of interest), or interactive (e.g., interrogation, self-disclosure). However, Berger (1987: 41) makes the point that "uncertainty is not reduced for its own sake." We become uncertain when we perceive a deviation from norms or expectations, because of expected future interaction, or for incentive value (we are motivated to reduce uncertainty about people who have reward power).

Uncertainty reduction theory accounts for the fact that much of our initial interactions are highly scripted. Our scripted interactions with shopkeepers, ticket agents, office receptionists, waiters, and so on obviate the need to deal with uncertainty. However, when we do not have a ready made script, we have to rely upon attributions. Berger and Bradac (1982) propose four models of uncertainty reduction. Each model begins with communication of some form. This, in turn, leads one to make a judgment about either the group membership of the communicator or the psychological trait/state of the speaker. This will then make it possible to determine the degree of similarity between self and communicator, which in turn will affect the level of uncertainty. If the level of uncertainty is tolerable, people will then engage in some strategy to reduce uncertainty. Research suggests that strategy selection is governed by beliefs about the efficiency and social appropriateness of the strategy (Kellerman and Berger, 1984).

Elaboration Likelihood

The Elaboration Likelihood Model of persuasion (ELM) (Petty and Cacioppo, 1986) has stimulated some recent language-attitudes research. A major idea here is that persons can focus on the arguments contained in persuasive messages when forming, maintaining, or changing attitudes (central processing), or they can rely upon extra-argument information, such as communicator credibility or attractiveness (peripheral processing). Under conditions of high distraction, for example, persons may find peripheral cues especially useful, whereas in situations where attitudinal decisions have crucial consequences, message arguments may be highly salient. One possibility is that language style may serve as a peripheral cue in some situations. Message recipients may not attend closely to arguments, but instead use their evaluative reactions to dialect, accent, and so on as a basis for decision making. Two studies demonstrated that linguistic power can affect message recipients' cognitive responses (findings consistent with ELM), but power of style did not affect persuasion **uniquely** under conditions of distraction (Holtgraves and Lasky, 1999) and low message relevance (Gibbons *et al.*, 1991); two-way interactions between power and distraction and between power and message relevance were not obtained, findings that do not support predictions of ELM with regard to power of style.

Information Processing Theory

Information Processing Theory has generated some interesting language-attitudes hypotheses. This is a general theory of attitude change constructed by McGuire (1968) and extended by Hamilton (1997). Persuasion is viewed as a process with six phases: exposure to a message, perception, orientation to the communicator and the position advocated, goal-directed processing, causal attribution to the communicator regarding the position taken and arguments made, and information integration (i.e., relating the message to the message recipient's established knowledge). The basic processes of message comprehension and message/source evaluation undergird these phases, and a general hypothesis is that comprehension affects evaluation. The communicator's language style becomes important during the exposure and perception phases, and it can affect causal attributions and, more generally, message/source evaluation. A specific causal hypothesis reflecting the theory is that linguistic specificity is directly related to perceived message clarity, both specificity and clarity facilitate judgments of the position advocated, and perceived message clarity is directly related to perceived personalization of the message. There is evidence supporting this hypothesis and indicating that these effects are mediated by channel immediacy (e.g., written versus face-to-face messages) (Hamilton, 1998). Linguistic specificity is a function of several factors, including breadth of the semantic category referenced, presence or absence of euphemisms and dysphemisms, and presence or absence of adverbial or adjectival modifiers (Hamilton, 1998: 112). Another hypothesis (Hamilton, 1997) describes the 'charisma sequence': some message feature, for example, language intensity, triggers judgments of source dynamism which, in turn, increases competence, then trustworthiness and thus liking for source.

Conclusion

As an area of study, language and social psychology occupies a niche between mainstream social psychology and linguistics. Developments in the field have provided powerful integrative theories, particularly in the form of ethnolinguistic identity theory, communication accommodation theory, and uncertainty reduction theories. However, more recent work has demonstrated the utility of more cognitive models of language processing. In the future, we expect that

further advances will be made in the social cognitive developments of the social identity approach in the form of the extension to social identity theory, self-categorization theory. Further developments will likely link communication accommodation and uncertainty reduction theories.

Social Semiotics

S Petrilli, University of Bari, Bari, Italy

© 2006 Elsevier Ltd. All rights reserved.

Social semiotics is a part of semiotics understood as the general science of signs. This statement is important to understand the place of social semiotics in the global framework of semiotics. According to Ferdinand de Saussure, the general science of signs, '*sémiologie*,' coincided with the 'science qui étude la vie des signes au sein de la vie sociale.' But semiotics today has come a long way with respect to this conception. In *Semiotik/Semiotics: a handbook on the sign-theoretic foundations of nature and culture* (Posner *et al*., 1997–2004), semiotics is far broader than a science that focuses on signs in the sphere of sociocultural life. Semiotics is not only *anthroposemiotics* but also *endosemiotics* (semiotics of cybernetic systems inside the organic body on the ontogenetic and phylogenetic levels), *microsemiotics* (the study of metabolism in unicellular life forms), *mycosemiotics* (semiotics of fungi), *phytosemiotics* (semiotics of plant life), *zoosemiotics* (semiotics of interactions among animals), *machine semiotics* (semiotics of sign processing machinery), *environmental semiotics* (the study of the interaction between the various species and environment).

Social semiotics today must consider its place in the universe of signs. Nor is it sufficient to consider the connection between one individual and another in a given society and culture. Dominant approaches to semiotic inquiry now refuse the idea of the individual as a separate and self-sufficient entity, and not only on a social level. The body of an organism in the micro- and macrocosm, in nature and culture, is not an isolated biological entity, it does not belong to the individual, it is not a separate and self-sufficient sphere in itself. The body is an organism that lives in relation to other bodies and as such it is intercorporeal and interdependent. The individual's relations transcend the individual sphere as well as the social sphere, culture, that is, the general anthroposemiosic sphere. The global character of social relations in the present-day world involves sign situations that not only are international, intercultural, and interethnic; they also cut across abstract separations, such as the dichotomy natural vs. historico-social life, and evidence how human life shares the same destiny as all of life on the planet.

An approach to semiotics that is at once global and detotalizing presupposes dialogue and otherness. In other words, social semiotics presupposes the capacity for listening to the other, opening to the other, hospitality. 'Opening' is not only understood in the quantitative sense (i.e., with reference to the omnicomprehensive character of global semiotics), but also in the qualitative sense. Otherness obliges the totality to reorganize itself ever anew in a process related to 'infinity,' as Emmanuel Levinas teaches us, or to 'infinite semiosis,' as says Charles S. Peirce. The relation to infinity is far more than cognitive: beyond the established order, the symbolic order, convention and habit, it presupposes a relation of involvement and responsibility. This relation to infinity is a relation to what is most refractory to the totality, a relation to the otherness of others, the other person. Nor is the expression 'other person' understood in the sense of another Self like ourselves, another *alter ego*, an I belonging to the *same community*. Instead, reference is to the other in its extraneousness, strangeness, difference – the alien self. In spite of all efforts made by identity, of all guarantees offered by identity, Self cannot be indifferent in the face of difference thus described.

All semiotic interpretations by the student of signs – especially when operating on a social semiotic level – must keep account of the dialogic character of the relation with the other. Dialogism is a fundamental condition for a social semiotic approach with a global orientation. And rather than englobe the particular and the local, in the light of such an approach these are enhanced in their dynamic relation to the detotalized totality.

Social-Cognitive Basis of Language Development

M Tomasello, Max Planck Institute, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

Linguistic communication is a form of social interaction. It is a special form because it is mediated by linguistic symbols. Linguistic symbols are social conventions used by human beings to direct one another's attention to various aspects of their shared environment. Different societies have created different sets of linguistic symbols – at the moment there are approximately 6000 languages in the world – and indeed the linguistic symbols of each society evolve fairly rapidly over historical time as speakers modify existing ways of talking to meet changing communicative circumstances.

Children are exposed to the linguistic conventions of their speech community as they interact socially with mature language users. To acquire productive use of linguistic conventions children must have the social-cognitive skills to:

- participate with others in the joint attentional interactions that provide a common referential ground for symbolic communication (joint attention);
- understand the communicative intentions of others as embodied in linguistic symbols of various types (intention reading);
- take the perspective of others in tailoring the choice of linguistic expression to particular communicative contexts (perspective taking);
- collaborate with others in coconstructing a conversation with a shared topic and 'relevant' contributions of new information (communicative collaboration).

Other animal species do not possess any of these social-cognitive skills – at least not in their human form – and that is the main reason why they are unable to create or to learn a human language (Tomasello, 1999, 2003).

Joint Attention, Intention Reading, and Word Learning

The social-cognitive foundations for language acquisition begin to emerge in human ontogeny near the end of the first year of life in various of infants' nonlinguistic activities. Most importantly, at around 9 months of age infants begin to interact with other people triadically around a 'topic' of mutual interest ('the primordial sharing situation'). Thus, they begin to follow others' attention to external events and entities (Tomasello, 1995), to direct others' attention to external events and entities using nonlinguistic gestures for both imperative and declarative purposes (Bates, 1979), and to engage with others in relatively extended bouts of joint attentional activity (Bakeman and Adamson, 1984). Other animal species engage rarely, if at all, in triadic communicative interaction.

Children acquire their earliest linguistic conventions within the context of routine joint attentional activities such as having a meal together, taking a bath together, going for a ride together in the car, and so forth (Bruner, 1983). These routines serve as necessary scaffolding because linguistic symbols are associated with their communicative functions only conventionally – which presents a unique learning situation. That is, no matter how intelligent a child is, she cannot on her own figure out what some sound means, but rather she must experience a speaker using that sound for the purposes of communication and then determine why, toward what communicative end, he is using it. This determination requires the child to have some nonlinguistic access to the kinds of thing the adult may be communicating about. This is provided by the joint attentional activity, which basically defines 'what we are doing' and so determines a kind of domain of relevance. For example, if a child hears the new word *gavagai* from an adult out of the blue, so to speak, she will not learn it because she has no idea why, for what communicative purpose, the adult is using this word. But if she and the adult

Linguistic communication is a form of social interaction. It is a special form because it is mediated by linguistic symbols. Linguistic symbols are social conventions used by human beings to direct one another's attention to various aspects of their shared environment. Different societies have created different sets of linguistic symbols – at the moment there are approximately 6000 languages in the world – and indeed the linguistic symbols of each society evolve fairly rapidly over historical time as speakers modify existing ways of talking to meet changing communicative circumstances.

Children are exposed to the linguistic conventions of their speech community as they interact socially with mature language users. To acquire productive use of linguistic conventions children must have the social-cognitive skills to:

- participate with others in the joint attentional interactions that provide a common referential ground for symbolic communication (joint attention);
- understand the communicative intentions of others as embodied in linguistic symbols of various types (intention reading);
- take the perspective of others in tailoring the choice of linguistic expression to particular communicative contexts (perspective taking);
- collaborate with others in coconstructing a conversation with a shared topic and 'relevant' contributions of new information (communicative collaboration).

Other animal species do not possess any of these social-cognitive skills – at least not in their human form – and that is the main reason why they are unable to create or to learn a human language (Tomasello, 1999, 2003).

Joint Attention, Intention Reading, and Word Learning

The social-cognitive foundations for language acquisition begin to emerge in human ontogeny near the end of the first year of life in various of infants' nonlinguistic activities. Most importantly, at around 9 months of age infants begin to interact with other people triadically around a 'topic' of mutual interest ('the primordial sharing situation'). Thus, they begin to follow others' attention to external events and entities (Tomasello, 1995), to direct others' attention to external events and entities using nonlinguistic gestures for both imperative and declarative purposes (Bates, 1979), and to engage with others in relatively extended bouts of joint attentional activity (Bakeman and Adamson, 1984). Other animal species engage rarely, if at all, in triadic communicative interaction.

Children acquire their earliest linguistic conventions within the context of routine joint attentional activities such as having a meal together, taking a bath together, going for a ride together in the car, and so forth (Bruner, 1983). These routines serve as necessary scaffolding because linguistic symbols are associated with their communicative functions only conventionally – which presents a unique learning situation. That is, no matter how intelligent a child is, she cannot on her own figure out what some sound means, but rather she must experience a speaker using that sound for the purposes of communication and then determine why, toward what communicative end, he is using it. This determination requires the child to have some nonlinguistic access to the kinds of thing the adult may be communicating about. This is provided by the joint attentional activity, which basically defines 'what we are doing' and so determines a kind of domain of relevance. For example, if a child hears the new word *gavagai* from an adult out of the blue, so to speak, she will not learn it because she has no idea why, for what communicative purpose, the adult is using this word. But if she and the adult

are giving her a bath together and the adult looks at the rising water level and says *gavagai* while turning the faucet off, there are only a limited number of plausible meanings for this expression – assuming it is relevant to the activity. It is thus not surprising that Carpenter *et al*. (1998) found that the size of children's early vocabularies is highly correlated with the amount of time they spend in joint attentional engagement with others.

For the child to be able to zero in on a single one of the plausible meanings of a new expression used within a joint attentional activity, she must be able to read the communicative intentions of other people more specifically; that is, she must be able to determine specifically what the adult intends for her to attend to. Initially, it is very helpful if adults do most of the work and follow into the child's already existing focus of attention when using a new expression (see Tomasello, 1988 for a review). But as development proceeds, children become ever more skillful at determining adult communicative intentions in novel contexts in which the two of them are focused on different things. Thus, if an adult uses a novel word when he, the adult, is attending to one object and the child is attending to a different object, the 18-month-old child will follow the adult's attention to the object on which he is focused in determining the intended referent (Baldwin, 1993). Further, if the adult is picking his way through a toy box full of objects in search of a 'modi,' 18-month-old children will be able to pick out his intended referent by the fact that he rejects some objects and finally accepts one – despite the fact that he looks equally at them all. And if the adult uses a novel verb to announce an intended action ("Now, let's dack Ernie") and then performs one act on purpose and another by accident on Ernie – with different orders of these two across children – 24-month-old children know that the intended referent of *dack* is the one done on purpose (see Tomasello, 2001 for a review of these and similar studies).

Children's acquisition of linguistic symbols thus depends most fundamentally on their ability to participate in the joint attentional activities that create a common communicative ground with their interlocutor and on their ability to read the intentions of others in particular communicative contexts.

Perspective Taking and Construction Learning

The broader social purposes for which people use language are such things as greeting others, informing others, asking questions, requesting favors, and so forth. In many cases the speakers of a language have conventionalized entire grammatical constructions for the most frequently occurring of these functions, for example, English wh-questions for requesting information and imperatives for requesting favors. In addition, speakers use different conventionalized grammatical constructions depending on who the listener is and what she knows and expects. For example, if we are conversing about my sister and I want to tell you something that happened to her, I might very well use an English passive construction such as *She was sued by her landlord*. Or perhaps I learn that you erroneously believe that my sister's therapist sued her, in which case I might correct you by using a cleft construction such as *It was her* ***landlord*** *that sued her.* If we have been talking about something else I might introduce the topic by using some kind of presentational construction like *You know my sister's landlord, he* . . . . In theories of language such as cognitive linguistics and construction grammar these kinds of constructions are, like words, linguistic symbols that pair a linguistic form and communicative function (i.e., the communicative intentions the symbol embodies). Children thus learn these constructions in a way that is not totally different from the way they learn words, that is, by observing people use them for particular communicative functions – which they determine by intention reading, including the subintentions of any subconstructions involved (e.g., noun phrases, locative phrases; see Langacker, 1987; Goldberg, 1995).

From a social-cognitive point of view, the most interesting thing about the acquisition of constructions is that children must learn when to use which one, and this often involves a subtle assessment of the knowledge and expectations of the listener. For instance, in their acquisition of noun phrases 2-year-old children learn to do such things as use pronouns to refer to an entity when they are jointly attending to that entity with their listener, but use a lexical noun with a determiner (or even a relative clause) when the two of them are not jointly attending (see Tomasello, 2003: Chap. 6 for a review). Similarly, to learn to use a cleft construction (e.g., *It was Jeffrey that took the cookies*) children must be able to tell that their listener is currently under the mistaken impression that someone else took the cookies and then choose a construction that makes contact both with the mistaken impression and its correction. Saying *The vase broke* enters the event from the perspective of the vase whereas saying *I broke the vase* enters it from the perspective of me and my activity (Budwig, 2000).

In all these cases, then, children must learn the perspective, in the broad sense of that term, that a construction embodies, and the communicative situations in which it is appropriately used. They do this

initially in a very local and item-based way. For example, they might initially be able to alternate between the object's and the actor's perspectives only with the verb *break*, with extension to other verbs coming only very gradually (Tomasello, 2000).

Communicative Collaboration in Conversation

As children are acquiring the various symbols and constructions of their language they are at the same time learning how to use these symbols and constructions to communicate more effectively in extended conversational interactions with other people. Conversational and discourse skills are concerned not so much with the mastery of the grammaticized and conventional aspects of a language, but more with the mastery of strategies for using those constructions effectively to manage the flow of information across turns in a developing conversational interaction. Skill at conversation involves such things as taking turns appropriately, managing the conversational topic effectively, and repairing a conversational interaction when it breaks down.

Becoming a skilled conversationalist requires children to read the intentions and take the perspective and role of their listener in many complex ways in novel contexts, and so many conversational skills do not fully develop until late in the preschool period. Thus, at 2 years of age only a minority of children's utterances are semantically contingent on the adult's previous utterance, and very few of their turns include reference to both the preceding topic and also some new information – the prototype of a mature conversational turn. When they do engage in a relatively extended conversation on a single topic, 2-year-olds typically take only one or two turns per conversation, with this value doubling by about 4 years of age (Pan and Snow, 1999).

Conversation is a form of collaboration in the sense that from a very early age there is a 'negotiation of meaning' between the two conversationalists (Golinkoff, 1983), and there are requests for clarification back and forth when one person does not understand something in the other's formulation. Almost from the beginning of the language acquisition process, young children both respond to requests for clarification and, less frequently, request clarification of others in their conversations (see Tomasello, 2003: Chap. 7 for a review). This again requires sophisticated skills of intention reading and perspective taking.

Collaborative activities, either nonlinguistic or linguistic, thus require participants to have a common goal and to work together in coordinated ways to achieve it. This coordination is not a foregone conclusion, and indeed animals that communicate with one another in fairly sophisticated nonsymbolic ways still do not engage in the back and forth of conversational interaction (and often engage very little in collaborative, turn-taking interactions of any kind).

Conclusion

Children thus employ their species-unique social-cognitive skills to acquire and use a natural language – skills of joint attention, intention reading, perspective taking, and communicative collaboration. But in the process of acquiring a language, children are led to consider various particular intentions and perspectives that they almost certainly would not have created on their own: the very same animal is referred to on different occasions as a dog, an animal, a pet, or a pest; the very same action is referred to as running, fleeing, chasing, or exercising. Acquiring a natural language in interaction with other persons thus leads young children to create some species-unique forms of cognitive representation, namely, perspectival cognitive representations (Tomasello, 1999).

A number of theorists have also proposed that conversation and discourse might play an important role in children coming to have a 'theory of mind,' that is, in coming to view other persons as mental agents who can have beliefs (including false beliefs) about the world (Harris, 1996). Thus, to engage in true conversation children must in some sense simulate the perspective of other people as they express themselves linguistically, and thus the back and forth of discourse involves the child in a constant shifting of perspectives from her own to that of others and back again – which helps her to construct both social norms and individual attitudes and beliefs (Tomasello and Rakoczy, 2003).

And so the relationship between children's social cognition and language is not one way. They must have certain social-cognitive skills to acquire a language, but then engaging in linguistic communication leads them to create new social-cognitive skills. Acquiring a language may thus be seen as another manifestation of the basic dialectic in which children are biologically prepared for culture, but then participation in culture – whose artifacts embody the skills, attitudes, and perspectives of other individuals – takes their cognitive skills to new places.

Socialization

J Cromdal, Linköping University, Linköping, Sweden

© 2006 Elsevier Ltd. All rights reserved.

In anthropology, sociology, as well as social psychology, studies of children are traditionally found under the heading of 'socialization.' In the widest sense, this term refers to an indefinite array of social events taking place in ordinary life surroundings as well as in institutional settings, representing events through which people become skilled in the ways of society. However, researchers within the social and behavioral sciences have settled for a much narrower conceptualization, typically treating socialization as the process through which adults secure the transition of the youngest generation from childhood into ordinary membership of society.

For the early sociologists such as Durkheim and Parsons (*see* **Durkheim, Emile (1858–1917)**), who conceived of society largely in moral terms, socialization is primarily a matter of the individual internalizing a set of norms and values crucially shared by members of society. For sociologists and psychologists alike, socialization is the process through which the individual acquires a sense of a social 'self.' Within traditional social anthropology (e.g., Mead, 1930), this process is taken to also include the development of particular skills in relation to the socioeconomic order of a culture. Thus, the notion of socialization has provided sociologists and anthropologists with a way of accounting for the maintenance and reproduction of social order, and furnished psychologists with an axiomatic for understanding the individual's social as well as moral development (Tholander and Cromdal, 2005).

Norms, Rules, and the Maintenance of Social Order

One of the central tasks of early sociology was to explain how societies are held together. Assuming that humans are born into society as virtually asocial beings, Durkheim (1979) came to the realization that the notion of mutual economic interdependence, with its resulting division of labor among members of society, is not enough to account for the maintenance and reproduction of social order. For society to be possible, there must be an underlying consensus

In anthropology, sociology, as well as social psychology, studies of children are traditionally found under the heading of 'socialization.' In the widest sense, this term refers to an indefinite array of social events taking place in ordinary life surroundings as well as in institutional settings, representing events through which people become skilled in the ways of society. However, researchers within the social and behavioral sciences have settled for a much narrower conceptualization, typically treating socialization as the process through which adults secure the transition of the youngest generation from childhood into ordinary membership of society.

For the early sociologists such as Durkheim and Parsons (*see* **Durkheim, Emile (1858–1917)**), who conceived of society largely in moral terms, socialization is primarily a matter of the individual internalizing a set of norms and values crucially shared by members of society. For sociologists and psychologists alike, socialization is the process through which the individual acquires a sense of a social 'self.' Within traditional social anthropology (e.g., Mead, 1930), this process is taken to also include the development of particular skills in relation to the socioeconomic order of a culture. Thus, the notion of socialization has provided sociologists and anthropologists with a way of accounting for the maintenance and reproduction of social order, and furnished psychologists with an axiomatic for understanding the individual's social as well as moral development (Tholander and Cromdal, 2005).

Norms, Rules, and the Maintenance of Social Order

One of the central tasks of early sociology was to explain how societies are held together. Assuming that humans are born into society as virtually asocial beings, Durkheim (1979) came to the realization that the notion of mutual economic interdependence, with its resulting division of labor among members of society, is not enough to account for the maintenance and reproduction of social order. For society to be possible, there must be an underlying consensus

among its members concerning the most central values and beliefs that inform and crucially constrain social behavior. This assumption raised questions about how society's central norms and values are transmitted across generations, how in becoming part of society, children come to internalize these most central features of social life. For Durkheim, this task is handled by society's institutions: the family, the church and most importantly the school, which is responsible for the moral education of the child. (*see* **Institutional Talk**).

Following up on these ideas, Parsons (1951) sought to elaborate how societal norms and values are translated into concrete rules of behavior, i.e., how they inform and essentially govern people's actions. Central in his work is the notion of 'value orientation patterns,' which allow individuals to infer the expected forms of behavior from the social roles participants occupy in a variety of settings. This allows people not only to recognize what is expected of them when acting within their roles but also to assess other people's role performance. This is a crucial aspect of the normative nature of social structures, as it enables society's actors to impose social control on each other. Moreover, it allows adult members of society to socialize the children. In this way, the processes of social control and socialization operate within the social system toward an ideal state of equilibrium.

A Developmental Orientation

A notable feature of these early works as well as their subsequent applications is that the concept of socialization is almost exclusively applied to the study of children. In his work on society as a social system, Parsons readily acknowledged that socialization is a life-long process, only to argue later on the same page that sociological inquiry should remain focused on childhood, or the period of 'primary socialization.' It is during this period in life, Parsons argued, that the 'major value-orientation patterns,' comprising normative patterns of behavior, are 'laid down' within the social actor (Parsons, 1951: 208). These orientations to shared values were seen as foundational to an individual's 'basic personality structure,' and as such they would not undergo substantial change later in life. Among the specific processes of socialization, Parsons identifies such mechanisms as *reward-punishment*, *instruction*, and a set of *mechanisms of value-acquisition*, of which the most important one is the child's *identification* with the adult.

Parsons's integration of various streams of concurrent psychological reasoning within his systemic theory of society suggests that socialization theory is not a strictly sociological enterprise. Indeed, it provides something of a paradigmatic perspective for social and behavioral studies of children. Hence, issues of socialization have been addressed by virtually all the major psychological theories of development, and there are few major works within social anthropology that do not attend to the problem of cultural transmission across generations, often referred to as 'enculturation.' Common to all the traditional – and much of the contemporary – socialization research is a view of childhood as a period of transition, during which children gradually become (or fail to become) full-fledged members of society. In this way, socialization research trades on massively commonsensical and normative notions of children and childhood. At the same time, it provides a scientific foundation for these cultural beliefs.

Socialization: Critical Perspectives

One of the earliest criticisms of socialization theory appeared in Wrong's (1961) essay on the 'oversocialized conception of man,' in which he argues that the notion of socialization is used as an automatic account for any queries of social order:– Why does society hold together? – Because people are socialized to follow common rules of behavior. The problem here, according to Wrong, is the implication that, having been socialized into society, people have little choice but to follow its rules. Apart from its social determinism, this view renders sociological inquiry trivial.

Similar problems were addressed in Garfinkel's early ethnomethodological investigations (1967), in which he points out that sociological theory construes the member of society as a 'judgmental dope,' who 'produces the stable features of the society by acting in compliance with preestablished and legitimate alternatives of action that the common culture provides' (Garfinkel, 1967: 68). Garfinkel then proposes that in billing the member of society as a judgmental dope, social science scholars employ a variety of (research) procedures, designed to preclude the practical concerns of members in actual social situations. The concept of socialization can then be seen as an analytical resource to this end, in that it allows researchers to gloss over (Mackay, 1975), rather than investigate, the lived features of cultural (re)production. Indeed, the invisibility of actual practices of socialization is already built into Parson's sociological theory, in which he proposes that 'many features of the actual process of socialization of the child are obscure' (Parsons, 1951: 214).

A related set of problems in socialization theory pertains to the specific status of the child as social

actor, including, as we have noted, a general research bias toward issues of development. As Speier (1971: 188) points out:

> sociologists (and this probably goes for anthropologists and psychologists) commonly treat childhood as a stage of life that builds preparatory mechanisms into the child's behavior so that he is gradually equipped with the competence to participate in the everyday activities of his cultural partners, and eventually as a bona fide adult member himself.

Speier refers to this view as the 'classical' formulation of socialization because, although employed by researchers for 'scientific' purposes, it is rooted in folk beliefs about children. These beliefs form a set of ideological conventions, according to which children are treated as incomplete social participants, as 'incipient beings' (Durkheim, 1979). On this view, children's social skills are thought of in terms of incompetence, or at best, pre-competence, and therefore, children need to be guided into social life by adults.

Jenks (1997) proposes that most social theories adopt this adult-oriented perspective on children and therefore 'spectacularly fail to constitute the child as an ontology in its own right' (Jenks, 1997: 10). We should note that the adult perspective not only casts children as less-than-competent participants in society's business but also ascribes the problem of participation in social life *to the child* (Speier, 1976). One important implication of this interpretive imposition is that children's actions will be understood in ways that conform to, ratify and elaborate the biased, adult-folklore-oriented view of what goes on between children and adults. This in turn inevitably precludes not only any adequate understanding of children's social worlds but also inhibits an understanding of the joint interactional work in which both parties to adult-child exchanges must necessarily engage. Ironically, it is precisely these situated practices of action and reasoning that form the very basis of socialization (see Edwards, 1995, and Waksler, 1991, for further discussions).

These concerns led Speier (1971) to respecify the very notion of socialization as above all a matter of developing skills for participation in social events. This opens up for empirical investigation of socialization from within social events, by attending to the organization of talk-in-interaction. In this vein, pioneering ethnomethodological works by Sacks (1992, Vol. 1, Lecture 2, Spring 1966: *et passim*), Speier (1976), and Mackay (1975) demonstrate how children manage to participate in talk under overwhelmingly restricted conversational rights with adults. (*see* **Ethnomethodology; Sacks, Harvey (1935–1975)**.) In later years, analysts of social interaction have focused on the organization of talk within a range of activities within the peer group such as negotiations of local alignments and friendship relations (Goodwin, 1990; Whalen, 1995), teasing (Tholander, 2002), and the management of conflict (Cromdal, 2004; Maynard, 1985). (*see* **Organizational Discourse; Institutional Talk.**)

The focus on socialization within the peer group arose out of an increasing sociological interest in children's play. As Sutton-Smith pointed out, "Peer interaction is not a preparation for life. It is life itself" (1982: 75). In this vein, interpretive sociologists and social psychologists argued that it is through the management of peer group concerns that children appropriate the values and beliefs of the adult world, and it is through these necessarily communicative practices that children produce their own unique peer culture (e.g., Corsaro and Eder, 1995; Harris, 1995).

The necessity of studying the communicative practices within the peer group is also highlighted by language-oriented ethnographers, who not only demonstrate how children are socialized through language but, crucially, demonstrate how the children are socialized to use language appropriately within distinct social groups (e.g., Ochs and Schieffelin, 1995). These studies, commonly known as 'language socialization,' provide a critical perspective on the relation among language, culture, and communicative practice, and its role in children's language acquisition.

In 1990, James and Prout outlined a social constructionist framework for the study of children and childhood. This interdisciplinary enterprise was designed to revitalize and redefine the status of childhood on the social studies research agenda, and was accordingly launched as a 'new paradigm for the study of childhood' (James and Prout, 1990: 5). Echoing the early ethnomethodological critique, researchers embracing this orientation strongly dispute the traditional view that studies of childhood are interesting only insofar as they tell us something about future adulthood, along with its allied notion of children as passive recipients of culture. Instead, within this approach – sometimes referred to as 'the new social studies of childhood' – researchers insist that children be recognized as social agents, capable of constructing their own social worlds. A further interest is in understanding the relations between children's social worlds and society's institutions, such as the family, school, or any other of the adult-dominated spheres of social life in which children routinely participate. Stressing the constructed nature of cultural conceptions of children and childhood, researchers clearly

recognize that this process of construction is part and parcel of everyday interactional practices. However, although James and Prout emphasize the need for empirical studies to equal the theoretical development of this enterprise, analyses of situated interactions through which children create their peer cultures within society have hitherto been scarce. Hence, the current challenge for studies of children and childhood lies in exploring the overwhelmingly language saturated practices through which children take part in society's business.

Socialization: Second Language

Second Language Socialization

Socialization refers to the interactional processes through which a child or other novice develops the competence required for participation in the social life of a particular community or communities, including routine cultural practices, such as language and literacy activities, and local preferences for action, thought, and emotion. These processes occur in large part through language, the primary symbolic medium of cultural reproduction and transformation. Language socialization researchers invoke Whorfian views of linguistic relativity in articulating the view that "acquiring a language is part of a much larger process of becoming a person in society" (Ochs, 2002: 106). Accordingly, the language socialization paradigm is concerned with two interconnected phenomena: how children and other novices are socialized to use language and how these same individuals are socialized through the use of language. Language socialization research strives to relate individual processes to broader sociocultural contexts, seeking a maximally holistic perspective while simultaneously attending to the microlevel details of language use.

Background and Key Concepts

Originally articulated nearly two decades ago (Ochs and Schieffelin, 1984), this paradigm has retained an emphasis on the dialectic of language learning and socialization. Early language socialization research emerged as a branch of linguistic anthropology, opening new analytic pathways, through the combined use of ethnography and microlinguistic analysis, toward an understanding of first language and literacy development in childhood. Focusing on young children acquiring their L1 in diverse sociocultural settings (Ochs, 1988; Schieffelin and Ochs, 1986), and on relationships between culturally specific patterns of language socialization at home and in school (e.g., Heath, 1983), this research clearly documented the cultural specificity of language and literacy socialization practices and their developmental consequences during the transition from home-based to schooled activities. In subsequent years, language socialization research has expanded beyond its original emphasis on first language learning in childhood, incorporating studies of second and multiple language learning across the life span.

Inspiration for the genesis of the approach is often traced to seminal work on interactional and communicative competence by Gumperz (1982) and Hymes (1972), especially Hymes' formulation of the construct of communicative competence. To recall, Hymes opposed the view that only knowledge of formal structure was relevant to a theory of competence, arguing instead that competence consists of **variable** knowledge about patterns of language **use**. "Communicative competence involves knowing not only the linguistic code, but also what to say to whom, and how to say it appropriately in any given situation" (Saville-Troike, 2003: 18). Additional disciplinary sources of language socialization research are to be found primarily within scholarly domains privileging various integrated views of language and culture, including, as noted above, linguistic anthropology, but also sociocultural–historical psychology, discourse analysis, and, more recently, cultural and practice theory.

Second language socialization research draws its views on cognition as an integrity of language, mind, and society from sociocultural psychology as originally outlined by Vygotsky (1962, 1978) and Leontiev (1981), with its emphasis on the development of higher-order cognitive functions from the outside in, that is, through social interaction with adults or other experts where performance is assisted. Novices are seen to develop capacities through active and selective participation in social practices at various degrees of engagement (from legitimate peripheral to full participation) and, in so doing, to transform not only their own cognition, but also the qualities of the practices themselves (Lave and Wenger, 1991).

A perspective on language integrating linguistics and social practice is taken from discourse analysis, a field of linguistics that emphasizes the study of language in use, examining how the elements of language systems are used for communicative purposes within and across particular social and cultural contexts. "Language is seen as fully integrated into sociocultural behavior, as both the result and the creator of context and structure" (Watson-Gegeo and Nielsen, 2003: 163).

In recent years, language socialization research has been influenced by "...the poststructuralist realization that learning is a non-linear, relational human activity, co-constructed between humans and their environment, contingent upon their position in space and history, and a site of struggle for the control of power and cultural memory" (Kramsch, 2002: 5). Poststructuralist and critical theories attempt to unite research on language and power and thereby to

enhance the relevance of this research through agendas of social critique. These approaches highlight the role of language as symbolic capital and the subtle mechanisms by which power is circulated and reproduced in the discourse of socialization practices. Whereas language socialization was once portrayed as inevitable, desirable, and uniformly accessible, many researchers are now sensitive to the dynamic and negotiated nature of the process, including the possibility that novices may not have ready access to socialization, and the fact that they are endowed with agency (to accept, accommodate, resist, or reject socialization processes).

Foci and Methodologies

A constant in language socialization (LS) studies is their emphasis on developmental processes and their longitudinal design, requiring selection of research sites believed to be places of transformation, whether such change is observed in classrooms or chatrooms, in homes, schools, or workplaces. Research involving educational contexts has examined foreign and second language classrooms and participants of varying age, but has also examined the role of socialization practices in technology-enhanced learning environments, study-abroad programs, and adult language and literacy courses. The research on second language socialization is not limited to educational contexts, however, but also includes studies in homes, workplaces, and bilingual or multilingual communities.

Whereas the original methodology combining ethnography and microlinguistic analysis has remained at the core of the approach, language socialization research has also been enriched and refined in the intervening years through inclusion of a variety of definitional constructs, data elicitation practices, and analytic procedures. Thus, ethnographic approaches, in particular the ethnography of communication (EC), feature prominently in the literature on second language socialization. However, this literature is characterized by great variety in the choice of theoretical and analytic emphasis. Some studies take their primary inspiration from sociocultural psychology, examining the mediating role of language in the development of higher-order cognitive functions as individuals participate in 'activity systems'. Other studies focus less on the achievement of a 'thick description' of the surrounding sociocultural context (Geertz, 1973) and more on detailed analysis of particular discourse practices, often in second language classrooms. Still others, often inspired by poststructuralist theories of second language learning, investigate autobiographical representations of language socialization as they are presented in narrative and other texts.

Language socialization research varies considerably with respect to focal scale. Some studies involve minimal engagement with large numbers of participants, whereas others scrutinize the activity of one participant in multiple ways. Some studies examine the activities of participants in a range of contexts, whereas others confine their perspective to one (the classroom, the chatroom, the workplace). Time frames for longitudinal studies also vary considerably, with some studies emphasizing microgenesis of skills and capacities over relatively short developmental periods, such as one academic semester, and others attempting to trace ontological or developmental histories over periods of years or entire life spans.

Overview of Second Language Socialization Research

The overview of second language socialization research presented here is organized by primary methodological emphasis. Although division of studies into such categories is admittedly somewhat artificial, risking simplification, this descriptive account also provides a clear organizational framework for characterizing how differing epistemological goals and methodological resources are organized in illustrative individual studies. Therefore, the review begins with studies that are primarily ethnographic in orientation and then proceeds to examine the activity-theoretical approach, research examining socialization in second language classroom discourse, and investigations based on narrative study.

Ethnographic Approaches

As defined by Duff (2002), the EC is a "composite of approaches" (p. 292) for conducting qualitative or interpretive research on communication within or across cultures. EC combines etic and emic analyses of communication (i.e., outsider's and insider's views) as well as macro- and microanalyses of discourse in order to examine what a speaker needs to know in order to communicate effectively within a particular speech community and how he or she learns to do so (Saville-Troike, 2003). Ethnographic research normally requires prolonged engagement with the community under study and an effort at data triangulation, as well as careful observation of authentic communicative practices in their naturally occurring context.

Within ethnographic approaches, microlevel analyses of discourse are organized around the "communicative event" as the basic descriptive unit,

defined by "a unified set of components throughout, beginning with the same general purpose of communication, the same general topic, and involving the same participants, generally using the same language variety, maintaining the same tone or key and the same rules for interaction, in the same setting" (Saville-Troike, 2003: 23). Within contemporary second language socialization research, routine cultural practices are often mined in attempts to uncover the cultural or ideological underpinnings of everyday language and the processes by which accompanying values or worldviews are inculcated in children or other novices.

Thus, in many cases, data elicitation begins with a multimethod, holistic approach to thick description (Geertz, 1973) of socialization practices, followed by a choice of relevant communicative events based on this emic analysis. These events are then observed closely and repeatedly as they are audio- or video-recorded and transcribed. The choice of method for microanalysis of socialization practices varies greatly, with some researchers opting for close analysis of emergent routines through conversation analysis and others choosing various other forms of discourse or interaction analysis.

The work of Duff (1995, 2002) offers several examples of ethnographic research, examining the interface between macro- and microlevels of educational discourse in secondary schools. Duff (1995) investigated the consequences of post-Soviet educational reform in English language immersion classes in a progressive Hungarian school. Duff's study revealed how macrolevel changes are reflected in the qualities of classroom discourse as students in English-medium history classes are socialized to accept the replacement of traditional oral assessment through recitation (*felelés*) by student-led activities and open-ended discussion. More recently, Duff (2002) performed an ethnographic study in a mainstream Canadian high school with a large proportion of students who speak English as a second language. Concerned with the creation of cohesive and harmonious school communities that nonetheless accommodate diversity, the study analyzed the sequential organization of talk in a social studies course, including the organization of turn taking, alignment, and other features of participation. Results revealed that the teacher's emphasis on social justice and empathy for others was enacted in her attempts to allocate turns equitably and to have all students, local and nonlocal, draw cultural connections based on personal experience. However, some ESL students often declined to participate in discussions where they were positioned in various ways as outsiders. Thus, the teacher's efforts to foster a cohesive classroom community in which all members participated were often unsuccessful.

Another exemplary ethnographic study was performed by Willett (1995), focusing on the participation of ESL children in the daily routines of a mainstream first-grade classroom in the United States. Willett investigated the qualities of interactional routines embedded in communicative events as four children acquire English in first-grade classroom. The study reveals how the "micropolitics of social interaction" (p. 475) in this case positioned the three girls in the study as successful learners, able to collaboratively appropriate desirable social, linguistic, and academic competence. The one male participant, however, needed a public status in order to build solidarity with other boys. Having first acquired the public and often crude language used by these boys, he was isolated from his peers and was subsequently deemed an excessively needy and problematic student.

Additional ethnographic studies of note have been carried out in a wide array of contexts. Studies of schooling include Moore's (1999) report of major discontinuities between community and classroom language socialization practices in a Cameroon village, a gap that contributes to widespread rejection of French-based schooling due to the inaccessibility of the French language. Miller's (1999) ethnographic study of ESL students' socialization in a mainstream Australian high school showed how Chinese students' use of English is not legitimated in the same way that it is for European immigrants.

Ethnographic studies of socialization in multilingual workplaces include, for example, Goldstein's (1997) study documenting the complex interaction of community resources and identities combining to limit access to English for Portuguese immigrant factory workers. An ethnographic case study by Li (2000) focused on the pragmatics of higher-stakes social communication, illustrating how one woman, a Chinese immigrant to the United States, came to internalize second language norms and develop communicative competence in English through participation and exposure to social interactions and assistance from experts and more competent peers.

A number of studies have examined the study-abroad sojourn as a context for language socialization. DuFon's (2000) study of the acquisition of linguistic politeness by U.S. sojourners in Indonesia revealed conflicts between the participants' own gender- and religion-related identities and the parallel options available in Indonesian. Talburt and Stuart (1999) discussed the manner in which an African American woman studying in Spain was subjected to continuous and humiliating emphasis on race and

sexuality in her interactions with Spaniards. Kline (1998) reported that American women studying abroad in France sought refuge in literacy following repeated encounters with sexist and hostile attitudes in the French-speaking community.

Sociocultural Theory and Language Socialization

Researchers primarily inspired by sociocultural perspectives, including activity theory (Vygotsky, 1978; Leontiev, 1981), have also begun to contribute to the literature on second language socialization. As Kasper has noted (2001), sociocultural theory and language socialization perspectives differ in their epistemological goal: whereas sociocultural theory aims to explain the mediating role of language (and other symbolic or physical tools) in the development of higher forms of cognition, language socialization strives toward an integrated account of language and culture acquisition. Nonetheless, the compatibility of the two perspectives derives from certain basic theoretical and methodological premises.

Just as LS strives to link individual processes to their sociocultural context, activity theory aims to overcome the traditional Cartesian dualism in the social science between the individual and surrounding social environment (Lantolf, 2000). It does so through the concept of mediation, or the observation that all human activity is mediated by culturally created physical and symbolic artifacts, including language.

Whereas LS studies aim to comprehend the norms of 'speech communities', activity theory defines the scope of sociocultural context in relation to the organization of practice. In any activity system, there exists a division of labor according to which certain roles are assigned or negotiated among the participants, and from which emerge the tacit or explicit rules that individuals and the community as a whole follow when interacting with one another and with mediating artifacts. The community of practice, an affiliated term, is seen to emerge from this division of labor and is the prime context in which individuals can work out common sense through (continuous) mutual engagement, a joint enterprise, and a shared repertoire of communicative resources (Wenger, 1998).

A crucial aspect of activity theory is its tracing of human behavior to historical rather than biological sources. The study of development is conceived as observation of genetic processes occurring over time. Language socialization research focuses primarily on two historical domains: ontogenesis (life history of individuals) and microgenesis (history of particular psychological functions over short periods of time). Thus, in practice, methodology of activity-theoretical research shares with LS a concern with prolonged, ecologically valid observation of human action.

From the perspective of activity theory, the meaning of human behavior arises from a need directed toward an object. The projection from the object to the outcome of the behavior is the motive. Motives are not always pre-established, but are dynamic and malleable and may be formulated in the process of activity itself.

An example of an activity-theoretical approach to language socialization is to be found in a study by Lantolf and Genung (2002) documenting the history of one graduate student's failure to learn Mandarin Chinese as a participant in a summer intensive Chinese course. The participant, P.G., a colonel in the U.S. Army, is an experienced language learner and teacher specializing in applied linguistics who is required to complete a requirement of six credits in a non-Western language. The study focuses on the conflict between P.G.'s historically formed self-image as a good language learner and the rules for interaction imposed by the activity system of the classroom and institution, where an authoritarian methodology is enforced. The study traces the transformation over time in this learner's motives for participating in the course. Whereas initially, P.G. defined her goal as developing communicative competence in Chinese, when her efforts to do so were repeatedly thwarted, she reframed her efforts as related to success in the course so as to meet the requirement and fulfill her obligation to the Army in securing a graduate degree. Thus, the study documents the dynamism of learner motives and accompanying social and cognitive activity as they evolved through participation in the course.

Classroom Discourse

In research on the qualities of classroom discourse, the socialization perspective serves to illuminate the nature and function of interaction as a cultural medium for language learning, focusing on both socialization through language and socialization to use language. For example, in a study of beginning ESL classes in the United States, emphasizing socialization through language, Poole (1992) demonstrated that routine interactional sequences led by the teacher bear significant resemblance to American caregiver language behavior in general. In this context, the teacher/expert coconstructed learner responses, attributed collective task accomplishment to individuals, and avoided an overt display of hierarchical asymmetry, thus expressing cultural preferences for conjecture on the mental states of others, individual

achievement, and suppression of power differentials. In a longitudinal study of similar aim, He (2003) examined the heritage Chinese-language school as a locus for socialization into cultural norms, focusing on the speech roles assigned to students. His study demonstrated the variability of novices' responses to socialization practices, showing how the opportunity to acquire Chinese and associated cultural values may be accepted or contested, even by young children.

For adults, socialization through a second language may present particularly complex problems related to language use and identity. Siegal (1996) presented a case study focusing on the role of learner subjectivity in the acquisition of sociolinguistic competence by European women learning Japanese in Japan. The study examined the conflict concerning sociolinguistic appropriateness experienced by one learner in conversation with her professor, where unequal power and positionality exerted influence on the quality of the interaction. Although she did understand the pragmatics of appropriate demeanor for a woman in Japanese society, in attempting to craft a voice for herself as a professional woman in Japanese, the student manipulated honorifics, modality, and topic control in ways that sometimes resulted in inappropriate language use.

Other classroom discourse studies orient their analysis more closely toward socialization to use language. Ohta (1999) probed interactional sequences in a Japanese-as-a-foreign-language classroom, emphasizing how these sequences engage learners' participation. The study tracked the pragmatic development of a learner over the course of 1 year, demonstrating that active and peripheral participation in the routines of classroom language use shaped the learner's ability to use the follow-up turn of the Initiation–Response–Follow-up routine to perform assessments and other responses to interlocutors' utterances. Hall (1995) scrutinized the interactive environment of a first-year high school Spanish class intended to provide speaking opportunities. The teacher's primary method of developing and maintaining topical coherence took place through repetition and chaining of a small number of lexical items. This practice differs considerably from the ways in which topics are discursively established and managed outside the classroom and produces a limited repertoire of communicative practices for the students. Students in such classrooms are not socialized to use discursive forms and functions for engaging in complex, extended talk about a topic and, indeed, in the absence of overarching topic relevance, these students cannot orient to the talk in ways that permit coherent contributions.

With the arrival and widespread use of computer-mediated communications (CmC) technology in the language classroom, researchers have also begun to investigate the implications of CmC use for language socialization. For example, in a study focused on the development of pragmatic competence in the use of address forms (du vs. Sie), Belz and Kinginger (2003) examined the discourse of intercultural exchanges in German and English in the context of a telecollaborative language course. Internet-mediated contact with peers who are expert users of German offered participants in the United States many opportunities for assisted performance in socially acceptable use of the address form system in German.

Narrative Study and Second Language Socialization

The contemporary literature includes a number of narrative approaches to second language socialization, aiming to understand how multilinguals represent the process of language socialization and how this process impacts on the qualities of communicative repertoires. Research on the representation of language socialization examines learners' autobiographical accounts of language learning. Based on representations of language learning history, often written by exceptional learners and users of multiple languages, this research offers insights into the ontogenesis of multilingualism over time and in relation to personal identity and historical context.

Pavlenko (2001), for example, adopted a poststructuralist approach to narrative study in a series of studies linking L2 socialization to various aspects of identity. Poststructuralism is "understood broadly as an attempt to investigate and to theorize the role of language in construction and reproduction of social relations, and the role of social dynamics in the processes of additional language learning and use" (Pavlenko, 2002a: 282). Narrative study is a socioculturally and sociohistorically situated literary analysis in terms of genre conventions, metaphors, and tropes (e.g., the self-made man, language learning as appropriation of voice) (Pavlenko, 2002b). Pavlenko (2001) posited cross-cultural differences in societal conceptions of normative gender-related identities. Based on a corpus of 30 second-language learning stories, Pavlenko analyzed learners' encounters with ideologies of gender and their associated discursive practices. She explored the dilemma of border crossers who find themselves in situations where their previous subjectivities cannot be legitimately produced and understood and who must choose to resist or produce new social identities, beginning with perception and critical examination of these identity options, through the processes of choosing

assimilation or resistance and of undergoing gender socialization.

Narrative approaches may also be applied to the study of bilingual communicative repertoires, as exemplified in the work of Koven (1998) examining the performance of identity in narrative by Portuguese–French bilinguals. The study involved elicitation of the same oral narratives of personal experience in Portuguese and French, with analysis of communicative style and use of register in each. Development of communicative repertoires in each of the two languages was closely tied to the sociocultural context of socialization, such that, in effect, the participants appeared to be performing different "selves" in each of their two languages. Having grown up in Paris, with family ties and frequent visits to rural Portugal, when narrating in French the participants employed contemporary urban speech styles expressing progressive values and gender roles in which, for example, women's self-expression is relatively unconstrained. When narrating in Portuguese, however, the same participants employed speech styles characteristic of rural settings and presented a more conservative version of their identity.

Taken together, these narrative approaches represent a promising new direction in the study of language socialization as a complex, lifelong process with consequences for discursive performance of identity.

Conclusion

Within second language studies, language socialization is now represented in numerous domains, including bilingualism, multilingualism, and foreign language learning in homes, workplaces, and educational settings of various kinds. Edited volumes (Kramsch, 2002; Bayley and Schecter, 2003) and a summary article (Watson-Gegeo and Nielsen, 2003) have marked the general acceptance of language socialization perspectives. At the same time, this growth has not gone uncontested, largely because the disciplinary roots and epistemology of socialization research are seen as fundamentally incompatible with those of the field known as Second Language Acquisition (SLA). Kramsch (2002), for example, expressed this conflict in terms of basic conceptual metaphors, with SLA preferring the Learner as Computer, and language socialization, the Learner as Apprentice. Historically, she noted, there has been little communication between these fields despite the fact that in practice (e.g., the practice of language learning and teaching) the goals of each may be seen as complementary, as, for example, when the aim of second language instruction is expressed as communicative development that requires precise knowledge of grammar and lexis. It is to be hoped that the complementarity of these approaches will increase in salience as researchers continue to design investigations of language learning.

Language

'Linguistics' may be somewhat blandly defined as the study of language. Such a characterization leaves out the all-important formulation of how such study is to be conducted, and where exactly the boundaries of the term 'language' itself lie. Broadly speaking, different branches of linguistics are concerned with language structure, acquisition, and use. 'Sociolinguistics' is one of the branches that is concerned more with the use of language than the other two aspects. And unlike branches like pragmatics and discourse analysis, which are also concerned with 'use,' sociolinguistics lays particular emphasis upon the social embeddness of language. When we use the term 'language' as a general phenomenon, we refer to a system of arbitrary

symbols used for human communication. Having 'human communication' as part of the definition of language makes it impossible to study language comprehensively without due regard to the social context of speech. Such an emphasis was not always explicit in linguistics.

Antecedents of Sociolinguistics

While sociolinguistics as a specially demarcated area of language study dates only to the early 1960s (e.g., Paulston and Tucker, 1997; Shuy, 1997: 23, who cite the summer of 1964 as a crucial time), attention to the social was implicit in many earlier studies. It is possible that just as most linguists accept that scholarly linguistics was first practiced in ancient India, culminating in Panini's *Astadhyayi* (ca. 500 B.C.E.), Panini may prove a pioneer of sociolinguistics too. The suggestion has been made that Panini's rules are, *inter alia*, "sophisticated attempts at capturing the stylistic preferences among variants which are characteristic of any living language" (Kiparsky, 1979: 1). In terms of a continuous lineage for modern sociolinguistics, however, four western traditions have been most influential: historical and comparative linguistics, anthropology, rural dialectology, and the study of mixed languages.

Historical and comparative linguists became interested in modern speech forms (or 'dialects') for the possible light they could shed on theories of language change that had previously been based on written materials. Two branches of what is now called 'sociolinguistics' had strong 19th-century antecedents: the study of rural dialects in Europe and contact between languages that resulted in new 'mixed languages.' The work of Hugo Schuchardt (1882), Dirk Hesseling (1897) and Addison Van Name (1869–1870) challenged many of the assumptions of their contemporaries.

Even Saussure, who is most frequently associated with modern structuralism, stressed in his work that language was a 'social fact,' i.e., it belonged to a realm larger than that of the individual. A society is not just the lowest common denominator of its individuals. For Saussure, the concrete data of language (what he called '*parole*') are produced by individual speakers, but "language is not complete in any speaker; it exists perfectly only within a collectivity" (1959: 14).

In the early 20th century, structuralists in the United States were partly motivated by the need to describe rapidly eroding American Indian languages before they became extinct. Becoming acquainted with the cultural patterns of societies that were novel to them led scholars like Franz Boas, Leonard Bloomfield, and Edward Sapir to establish what became the foundations of studies of language, culture, and cognition. Such an anthropological perspective on language was a forerunner to some branches of sociolinguistics, especially the ethnographical approach.

The term 'sociolinguistics' appears to have been first used in 1952 by Haver Currie, a poet and philosopher who noted the general absence of any consideration of the social in the linguistic research of his day. Significant works on sociolinguistics appearing after this date include Weinreich's influential *Languages in contact* (a structural and social account of bilingualism; 1953), Einar Haugen's two-volume study of the social history of the Norwegian language in America (1953), and Joos (1962) on the dimensions of style.

Emphases in Sociolinguistics

Chomsky's emphasis in the 1960s on an approach that abstracted language away from everyday contexts ironically led to the distillation of a core area of sociolinguistics, which was opposed to his conception of language. In a now infamous passage, Chomsky (1965: 3) argued that linguistic theory should be concerned primarily with an ideal speaker-listener in a completely homogeneous speech community, who knows its language perfectly and who is unaffected when applying his knowledge of the language in actual performance. While such an approach brought significant gains to the theory of syntax and phonology, many scholars felt that abstracting away from society could not lead to an encompassing theory of human language. This period marked a break between sociolinguists, who had an interest in language as communication within human societies, and the 'generativists,' who were interested in an idealized, nonsocial, psycholinguistic competence. Whereas the Chomskyan framework focused on what could be generated in language and by what means, the social approach tried to account for what can be said in a language, by whom, to whom, in whose presence, when and where, in what manner and under what social circumstances (Fishman, 1971; Hymes, 1971; Saville-Troike, 1982: 8). For the latter group, the process of acquiring a language is not just a cognitive process involving the activation of a predisposition in the human brain: it is a social process as well, that only unfolds in social interaction. The child's role in acquiring its first language is not a socially passive one, but one which is sensitive to certain 'environmental' conditions, including the social identity of the different people the child interacts with.

Dell Hymes (1971) was the principal objector to the dominance of Chomsky's characterization of what constituted the study of linguistic competence. He suggested that a child who might produce any

sentence whatever without due regard to the social and linguistic context would be "a social monster" (1974: 75) who was "likely to be institutionalized." Hymes coined the term 'communicative competence' to denote our ability to use language appropriately in different settings. His stress on language **use** was in strong contrast to Chomsky's focus on the abstract code. Hymes interest was not just in the production of sentences, but in characterizing the more social-bound aspects, such as the amount and volume of talk in different communities, acceptability of silence, rules for turn-taking, amount of simultaneous talk, etc. In this view, there are rules of use without which the rules of grammar are, at best, abstractions (at worst, Hymes said, "useless"). William Labov (1972: xiii), whose name features prominently in the discipline, expressed uneasiness about the term 'sociolinguistics,' since in his view there can be no linguistics that is not social. Still others are slightly suspicious of the term, since it privileges the linguistic over the social. One distinction that is sometimes made is that between 'sociolinguistics' (proper) and the 'sociology of language.' Some scholars believe that the former is part of the terrain mapped out in linguistics, focusing on language in society for the light that social contexts throw upon language. For these scholars, the latter ('sociology of language') is primarily a subpart of sociology, which examines language use for its ultimate illumination of the nature of societies. One writer (Fasold, 1984, 1990) has attempted to capture this formulation by writing two scholarly books: *The sociolinguistics of society* and *The sociolinguistics of language*. While there is some basis for such a partition, and something to be gained by it, in practice the boundaries between the two areas of study are so flexible as to merit one cover term (although, as in this entry, there is a slight difference in nuance between 'sociology of language' and the more common and general term 'sociolinguistics'). Sometimes the distinction between the two orientations is expressed by the terms 'macrosociolinguistics' and 'microsociolinguistics.' As in other subjects, notably economics, macrostudies involve an examination of interactions at a broader level (the focus is broad, as in the study of multilingualism or language attitudes in a community). Microstudies examine finer patterns on a local level (e.g., the details of conversational structure or accents in a particular community). Macrosociolinguistics tends to overlap with applied linguistics to some extent, especially regarding language policy, language use in the domain of education, and the interface between dialect and standard. The two fields are separated by the greater interest among applied linguists in the psychology of language learning, especially in second-language acquisition. There is also a more practical orientation among applied linguists in their educationally focused work on curriculum issues, materials development, language assessment, remediation, and so forth.

'A Language' as a Social Construct

Up to now we have been dealing with 'language' in the abstract, as a collective term. When we turn to 'languages' as individual entities, the possession of specific societies, we run into problems of definition. It may come as a surprise to the nonspecialist to learn that linguists are unable to offer a definition of what constitutes 'a language' (as against overlapping entities such as 'dialects'). For this reason the term 'variety' is employed as a neutral one, referring to any form of speech. The term 'variety' is particularly useful when the status of a speech form is unclear and one wishes to avoid prejudging the issue whether a given speech form is (in popular terms) a 'language' or a 'dialect.' In many instances the boundaries between languages are far from clear, especially where historical and geographical links are involved. Mutual intelligibility might seem a useful test of whether two varieties are distinct or not. In practice, however, it is almost always sociopolitical criteria that decide the status of a variety, rather than linguistic ones.

The case of Norwegian and Danish provides a clear illustration of the sociopolitical nature of the distinction between what counts as a language and what does not. For four centuries Norway was ruled by Denmark. Danish was considered the official language, with Norwegian speech having dialect status (i.e., it was considered a dialect of Danish). Upon Norway gaining its political independence in 1814, Norwegian was declared an 'official language,' distinct from Danish. The same has happened in what was formerly Yugoslavia, where Serbian and Croatian did not have independent status but were considered as 'eastern' and 'western' variants of the same language called Croato-Serbian (or Serbo-Croatian). With the bloody conflict that accompanied the break-up of the federation in the 1990s, differences between the two varieties were emphasized, and each of them have come to be considered independent 'languages.'

The opposite case is that of two varieties classified by linguists as distinct languages but considered the same by a community. Linguists consider creole forms of language to be separate systems from the languages they drew much of their vocabulary from (e.g., Jamaican Creole English is a different system from the standard English of southern England). Yet their coexistence of the two systems in the same society and the dominance of the more standard forms of English may not always lead to the recognition of the two as separate languages.

Language Is Not a 'Given'

The work of Le Page (1978) and Le Page and Tabouret-Keller (1985) has been influential in showing the potential diffuseness of the notion of 'a given language' and the way that the identities of groups of people are shaped by, and in turn shape, language use. For Le Page and Tabouret-Keller (1985: 14), linguistic behavior is "a series of **acts of identity** in which people reveal both their personal identity and their search for social roles." In this view, identity and language use are potentially fluid; and individuals have priority. Well-defined social groups may or may not exist beforehand. In the highly multilingual and heterogeneous communities they studied in the Caribbean, the researchers found it necessary to pay attention to the processes of emergence and disintegration of identities in relation to linguistic processes of focusing and diffusion. The terms 'focusing' and 'diffusion' are based on the imagery of the movie screen. Speech acts are acts of projection: the speaker projects his inner universe via a common language (with its nuances of grammar, vocabulary, and accent) or via a particular choice of language where choices exist (in multilingual settings). The speaker implicitly invites others to share his projection of the world, insofar as they recognize his language as an accurate symbolization of the world, and to share his attitudes toward it (Le Page and Tabouret-Keller, 1985: 181). The feedback he receives from those with whom he talks may reinforce his perceptions, or they may cause him to modify his projections, both in their form and content. To the extent that he is reinforced, his behavior in that context may become more regular, more focused; to the extent that he modifies his behavior to accommodate others, it may for a time become more variable, more diffuse. In time, however, the behavior of the group – that is, he and those with whom he is trying to identify – will become focused. The individual thus creates for himself patterns of linguistic behavior so as to resemble those of the group or groups which he wishes to be identified at different times. Le Page stressed four provisos to this hypothesis:

a. that one can identify the groups
b. that one has adequate access to the groups and the ability to analyze their behavioral patterns
c. that the motivation for joining the group must be sufficiently powerful and is either reinforced or lessened by feedback from the group
d. that one has the ability to modify one's behavior.

Le Page and Tabouret-Keller's model thus teases out the kind of variation evident in a society from its historical moments: is it a society in the making or in flux (diffuse) or is it, historically speaking, focused?

Sociolinguistics Is Not Prescriptive

Following studies like those of Le Page and Tabouret-Keller, sociolinguists now accept the idea that language is partly inherited and partly made and remade by its speakers. This perspective does not fit well with the traditional views one encounters among some writers, educationists, parents, and policy makers. The latter are more concerned with inculcating and transmitting a formal, written, and relatively homogeneous standard form of a language. There is nothing wrong with this ideal, provided that all citizens have access to the resources that are necessary for the mastery of the standard. Sociolinguists and linguists generally do, however, insist that inculcation of a standard norm among schoolchildren should not be accompanied by the denigration of the vernacular forms of language that pupils bring to the school. Children have in place a full language system, capable of considerable communicative nuance, before arriving at school. The vernacular has been demonstrated (see Labov, 1969) to be rule governed, even if it does not always meet the preconceived notions of correctness that two centuries of prescriptivism have inculcated among educators. Linguists (see Palmer, 1971; Crystal, 1971) have long shown the subjectivity and contradictions of the prescriptive rules insisted on by teachers ('don't split infinitives'; 'two negatives make a positive'). For English, these norms evolved over a period of time after considerable subjective pronouncements by 18th-century writers and grammarians (see Milroy and Milroy, 1985). They can easily be shown to have logical flaws. (In Latin, the infinitive occurs as a single word, which cannot be split; English, by contrast, expresses the infinitive in two words – *to* + verb – which occasionally permits an intervening adverbial element, as in *I want you to really try, for my sake*. The insistence that two negatives make a positive in English is nullified by prescriptivists' views of collocations of three negatives, as in *Nobody never said no such thing*. Prescriptivists would not accept this sentence as grammatical, even though the mathematics they appeal to makes it negative, rather than positive.) Prescriptive judgments ultimately serve upper- and middle-class interests, stamping their ideology as relating to 'taste,' 'discrimination,' and 'culture.' The sociologist Basil Bernstein (1974) argued that the orientation of children from working-class backgrounds toward language was 'restricted' compared to the relatively 'elaborated' norms of the middle classes. And since school success demanded the mastery of the latter, children from working-class backgrounds were less likely to succeed, given their limited access to those norms. Furthermore, their class position militated against

acquiring norms that are associated with forms of authority and/or lifestyles that they see no point in emulating. Bernstein's dichotomy between restricted and elaborated codes has been argued to be more an assumption than a linguistic reality (Labov, 1969; Edwards, 1979). However, his foregrounding of language and class issues in education is a lasting contribution to the sociology of language.

Society

A coherent theory of language in society can unfold only within a particular theory of society. Within sociology there are three dominant theories of human society, and there is little agreement between their adherents. The three theories (or sets of ideas about how society works) that have informed different approaches to sociolinguistics are 'functionalism,' 'Marxism,' and 'interactionism.'

Functionalism

Functionalism was the dominant theoretical perspective in western thought between the 1940s and mid-1960s. It pursued the view that a society may be understood as a system made up of functioning parts. To understand any part of society (e.g., the family or school), the part must be examined in relation to the society as a whole. Haralambos and Holborn (1991: 8) stressed the analogy with biology: just as a biologist might examine a part of the human body (e.g., the heart) in terms of its contribution to the maintenance of the human organism, the functionalist examines a part of society (e.g., the family) in terms of its contribution to the maintenance of the social system. The social system has certain basic needs (or functional prerequisites) that must be met if is to survive (e.g., food and shelter). The value of the function of any part of society lies in its contribution to the maintenance of the overall whole. There is a certain degree of integration between the parts (social institutions) that make up the society. Functionalists argue that the order and stability they see as essential for the maintenance of the social system are provided by 'value consensus,' i.e., agreement about values by members of society. In this view, two major occupations of the sociologist are the study of social subsystems and the value consensus that binds them together. Concepts stressed within (but not exclusive to) this brand of sociology that are particularly useful to sociolinguists include the following.

Culture Although the popular sense of this word stresses 'high' culture (e.g., musical, literary, and artistic achievements), in the technical sociological-anthropological sense, the culture of a society is "the way of life of its members; the collection of ideas and habits which they learn, share and transmit from generation to generation" (Linton, 1945). Culture in this sense is a "design for living" that defines appropriate or acceptable ways and forms of behavior within particular societies.

Socialization 'Socialization' refers to the process through which people learn the culture of their society. Primary socialization takes place in childhood, usually within the family. From a linguistic point of view, the peer group (e.g., the child's circle of playmates within and outside the home) soon overtakes the parents as the main reference group in transmitting linguistic behavior. Socialization continues into adulthood, and upon permanently entering a new society that differs considerably from one's own a person may undergo resocialization.

Norms and Values "A norm is a specific guide to action which defines acceptable and appropriate behavior in particular situations" (Haralambos and Holborn, 1991: 5), as evident in dress codes at school, at home, and at a party. In the course of socialization, 'norms' are inculcated by rewards (a sweet, a kind word) or punishments. Some norms become enacted in law to serve a larger society, e.g., a law forbidding nude bathing or the exposure of a woman's face in public in some societies. 'Values,' on the other hand, provide general guidelines regarding qualities that are deemed to be good, desirable, and of lasting worth. In many modern societies, the value placed on human life is a basic one that determines norms of behavior (e.g., standards of hygiene, settling of disputes, work safety regulations, etc.). Functionalist sociology proceeds from the premise that unless norms are shared, members of society would be unlikely to cooperate and work together. In this view, an ordered and stable society requires shared norms and common values.

Status and Role 'Status' refers to social positions that society assigns to its members (not just the high ones, as in popular parlance). Such a status may be ascribed, i.e., relatively fixed by birth (e.g., one's gender status, or aristocratic titles in some societies); or it may be achieved. The latter refers to statuses that result from some degree of personal endeavor, e.g., a career as a teacher or an athlete. In a caste-based society, one's occupation is ascribed, i.e., determined by birth; whereas in other societies it is achieved (i.e., by choosing one's training). According to Haralambos and Holborn (1991: 7) each status in society is accompanied by a number of norms that define how an individual occupying a particular status is expected to act. This group of norms is known as a 'role.'

Social roles regulate and organize behavior. In the course of a day, a person may play out several roles: that of teacher (at work), mother and wife (at home), client (with a bank), poet (at a leisure society), etc. These roles are defined by their interactive nature: the role of doctor usually assumes the existence (if not the presence of) a patient, that of mother the existence of the child, and so on. Each of these roles calls upon different forms of behavior, including linguistic behavior.

Marxism

Since the 1970s Marxist approaches in sociology have become increasingly influential. Differing sharply from the functionalist belief that all social groups benefit if their society functions smoothly, Marxism stresses fundamental differences of interest between social groups. These differences ensure that conflict is a common and persistent feature of society, not just a temporary disturbance of the social order (as functionalists believe). Karl Marx (1818–1883) stressed the economic basis of human organization, which could be divided into two levels: a base (or infrastructure) and a superstructure. The 'base' is determined by the forces of production (e.g., the raw materials and technology of a particular society) and the social relationships of production (e.g., social relationships that people enter into – such as manager and worker – to produce goods). The other aspect of society, the 'superstructure,' is made of the political, legal, and educational institutions, which are not independent of the base but shaped by it. Marx believed that all societies in historical times contain basic contradictions that preclude them from existing permanently. These contradictions, involving the increasing exploitation of one group by another (e.g., the exploitation of serfs by lords in feudal times), have to be resolved, since a social system containing such contradictions cannot survive unchanged.

The concepts that Marxists emphasize in their studies include social class; exploitation and oppression; contradiction, conflict, and change; and ideology and false consciousness. 'Class' denotes a social group whose members share a similar relationship to the means of production. Essentially, in capitalist societies, there is the ruling class, which owns the means of production (e.g., land, raw materials) and the working class, which must sell its labor power to earn a living. In feudal society the two main classes are distinguished relative to ownership of the land: the feudal nobility who owns it and the landless serfs who work it.

'Exploitation' in this theory is a technical term that stresses that the wealth produced by the labor power of workers is appropriated in the forms of profits by the ruling class. 'Ideology' within Marxist theory refers to the set of dominant ideas of an age: it emanates from the control of the ruling classes of the institutions of the superstructure. Such ideas serve ultimately to justify the power and privilege of the ruling class "and conceal from all members of society the basis of exploitation and oppression on which their dominance rests" (Haralambos and Holborn, 1991: 14). A clear example comes again from the feudal age in Europe, when the dominant concepts were honor and loyalty, which appeared to be the natural order and were celebrated in literature and implicit in superstructural institutions such as the law courts and education. Similarly, according to many theorists, in the capitalist age, exploitation is disguised by the ideology of equality and freedom, which appear to be not just sensible and true but natural and desirable. This, Marxists argue, conceals the reality that capitalism involves fundamentally unequal relationships: workers are not ultimately 'free' since they are forced to work to survive: all they can do is exchange one form of wage subordination for another.

Interactionism

A third school of thought within sociology, less influential than the previous two, proceeds from a bottom-up approach of examining small-scale encounters, rather than large-scale social systems. It seeks to understand action between individuals. Haralambos and Holborn (1991: 15) emphasized that interactionism begins from the assumption that action is meaningful to those involved, and that those meanings are accordingly not fixed, but created, developed, modified, and changed within the actual process of interaction. Not only is the meaning of a social encounter a negotiated entity, but the individual develops a 'self-concept' (or idea of oneself) according to the interaction processes he or she takes part in and according to the way he or she is evaluated therein. For the interactionist, social roles are not as clearly defined as within functional theory. Furthermore, interactionists argue that roles are often unclear, ambiguous, or vague. This may provide actors with considerable room for negotiation, improvisation, and creative action.

Much sociolinguistics has proceeded implicitly from a functionalist perspective of society, although it must be said that within the discipline the linguistic tends to overshadow the sociological. The latter is often considered useful, largely for informal background information and orientation. Marxist approaches are not typically emphasized in the West, and while the skepticism with which Marxist/communist political practice has come be to viewed

worldwide is understandable, from a scholarly point of view, many of the insights emanating from sociolinguistics do fit the Marxist critique of social systems quite well. Some sociolinguists have explored the linguistic ramifications of rule, control, and power. And class differences (which often criss-cross with gender or ethnicity) remain at the heart of studies of sociolinguistic variation. Interactionism, which may not seem as substantial a sociological approach as the other two, has nevertheless inspired some important work in sociolinguistics (*see* **Interactional Sociolinguistics**).

Language in Society, Society in Language

A concern for the 'human communication' aspect within the definition of language implies attention to the way language is played out in societies in its full range of functions. This function is not just 'denotational'; the latter term refers to the process of conveying meaning, referring to ideas, events, or entities that somehow exist outside language. Even while primarily concerned with this function, a speaker will inevitably give off signals concerning his or her social and personal background. Language is accordingly said to be 'indexical' of one's social class, status, region of origin, gender, age group, etc. The term 'index' here is drawn from semiotic theory (or the science of signs), in which it refers to a particular relation between a sign and the object it stands for (*see* **Semiotics: History**). In the sociolinguistic sense 'index' refers to certain features of speech (including accent) that indicate an individual's social group (or background); the use of these features is not exactly arbitrary, since it signals (or indexes) that the individual has access to the lifestyles that support that type of speech.

The relationship between region of origin, age, and – especially – social status and characteristic ways of using language are emphasized in 'variation theory,' as developed by William Labov (1966). Variationists use correlational techniques in revealing the relationship between linguistic variables (e.g., a vowel sound that has different variants that result in different accents) and social variables (age, gender, class, etc.). This is a vibrant and rigorous branch of sociolinguistics – to the extent that many characterize it as 'core sociolinguistics' or 'sociolinguistics proper.' Many sociolinguistics, however, argue that correlation does not capture the complex way in which language is intertwined with human existence. That is, they stress that talk is not just a reflection of social organization; rather, it is a practice that is one of social organization's central parts. This approach has informed much work on language and gender in linguistics. In earlier gender and language research (see Lakoff, 1975) the main aim was to demonstrate a broad linguistic split between the sexes. Subsequent researchers went beyond the descriptive framework to an action-research mode that popularized the argument that languages could be sexist – that is, they could discriminate against women by presenting things from a male perspective (see, e.g., Spender, 1990). Language thus not only reflects existing inequalities but also helps to sustain and reproduce them, unless challenged. Subsequent gender research has increasingly become more nuanced. Eckert (1989) stressed the interplay between gender and social class in setting up various overlapping identities. From anthropology and gay studies has come the notion that a simple two-way dichotomy is misleading; there are differing degrees of masculinity and femininity (Johnson and Meinhof, 1997; Kulick, 2000).

Similar arguments hold for sociolinguistic approaches to ethnicity. In some societies, ethnicity may be more salient than class stratification, and language may play a key role in reflecting and indeed in maintaining and 'reproducing' an ethnic identity. Ethnicity is notoriously difficult to define and may not be as objective a phenomenon as sometimes assumed. Edwards (1985: 8) quoted Weber (1968), who regarded ethnic groups as "those human groups that entertain a subjective belief in their common descent . . . it does not matter whether or not an objective blood relationship exists. Ethnic membership . . . differs from the kinship group precisely by being a **presumed** identity." Sociolinguists therefore argue against the notion of a 'primordial ethnicity' that one sometimes finds in the literature on language maintenance. After all, group identity can survive language shift and frequently does. On the other hand, it is difficult to imagine a sense of ethnicity that does not entail significant differences in language use (e.g., religious and cultural vocabulary and nuances of accent are well attested in ethnic dialects). Postmodern urban people of the 21st century frequently have multiple identities, playing out a number of roles in a single day, each of which may require different language choices.

The idea was once popular in linguistics and anthropology that language and thought are more closely entwined than is commonly believed. An extreme form of this belief is what has come to be known as the 'Sapir–Whorf hypothesis': It is not just that language reflects thought; but conversely, thought is influenced by the language one is 'born into.' Mind, according to this hypothesis, is in the grip of language, and so are social consciousness and organization. Edward Sapir, and – especially – Benjamin Lee Whorf were led by their studies of Amerindian

languages to argue that speakers of certain languages may be led to different types of observations and different evaluations of externally similar phenomena. According to Whorf (1956: 213), "we dissect nature along lines laid down by our native language." He said that using a language forced us into habitual grooves of thinking, almost like putting on a special pair of glasses that heighten some aspects of the physical and mental world while dimming others. One example provided by Whorf concerned the distinction between nouns and verbs in Hopi as opposed to English. The Hopi terms for 'lightning,' 'wave,' 'flame,' 'meteor,' 'puff of smoke,' and 'pulsation' are all verbs, since events of necessarily brief duration fall into this category. The terms for 'cloud' and 'storm,' on the other hand, are of just enough duration to qualify as nouns. Another of Whorf's striking examples concerns tense and time. Whereas English dissects events according to their time of occurrence (relative to the act of speaking), Hopi expresses other categories in the verb, notably the kind of validity that the speaker intends the statement to have: is it a report of an event, an expectation of an event, or a generalization or law about events?

The Sapir–Whorf hypothesis is a thought-provoking one, whose strong form suggests, among other things, that real translation between widely different languages is not possible. The hypothesis has proved impossible to test: how would one go about ascertaining that the perceptions of a Hopi speaker concerning the world are radically different from that of, say, a French speaker? Generative linguists today insist that there are limits (or parameters) along which languages vary. In appealing to the notion of deep structure (or its more recent mutations), this school of linguistics stresses an underlying capacity for language that is common to humans. What seem to be radical differences in the grammatical structure of languages are held to operate 'on the surface,' as mappings from an abstract and quasi-universal deep structure. Linguists feel safer in accepting a 'weak form' of the Sapir–Whorf hypothesis: that our language influences (rather than completely determines) our way of perceiving things. But language does not grip us so strongly as to prevent at least some individuals from seeing things from different perspectives, from forming new thoughts and ideas. Within sociolinguistics, studies in the way that languages influence each other (by borrowing and mixing) also cast doubt on the strong form of the hypothesis. As Gillian Sankoff (1986: xxi) put it: "my conviction [is] that in the long term language is more dependent on the social world than the other way around . . . Language does facilitate social intercourse, but if the social situation is sufficiently compelling, language will bend."

Types of Societies, Types of Language?

Societies may be characterized in terms of their complexity, as defined by their size, hierarchical organization, specialization of tasks, and interaction with other societies. It is important to note that there is no linguistic analogy to this. Languages cannot be arranged in a list from least complex to most complex. The structure of a language does not correlate with the complexity of the communities that typically use them. In terms of morphology, syntax, and semantics, a language of an isolated mountain-bound community in the Himalayas is no less complex than any of the six world languages of the United Nations. The poet-cum-linguist Sapir (1921: 219) put it as follows: "When it comes to linguistic form, Plato walks with the Macedonian swineherd, Confucius with the head-hunting savage of Assam." Sapir's student, Whorf (1956: 84), who was intimately acquainted with the structure of Hopi and other Amerindian languages, was just as emphatic, if less poetic:

> The relatively few languages of the cultures which have attained to modern civilization promise to overspread the globe and cause the extinction of the hundreds of diverse exotic linguistic species, but it is idle to pretend that they represent any superiority of type. On the contrary, it takes but little real scientific study of preliterate languages, especially those of America, to show how much more precise and finely elaborated is the system of relationships in many such tongues than is ours.

A reverse argument sometimes holds: people maintain that languages rich in inflections or in ways of combining basic grammatical units (morphemes) into words are perhaps too complex to function as languages of wider communication. Conversely, they suggest that the inflectional simplicity of English enables it to be effective as a language of international transactions. Several things are wrong with this argument. In the first place, notions of complexity should not be limited to the morphology of a language. Modern linguistics emphasizes the enormously complex organization of all languages. One language might appear to be morphologically richer on the surface, but a relatively simpler morphology (as with English) has to be made up in other components of the grammar – in the syntax and lexicon. If we are to look for reasons for the spread of one language over another, the wrong place to start would be the structure of the language, as Edwards (1995: 40) forcefully suggested:

> It is [...] clear, to the modern linguist at any rate, that these varieties [dominant languages] achieved widespread power and status because of the heightened fortunes of their users, and not because of any intrinsic linguistic qualities of the languages themselves. The most common elements here have to do with military, political and economic might, although there are also examples in which a more purely cultural status supports the lingua franca function. However, in this latter case, the cultural clout which lingers has generally grown from earlier associations with those more blatant features just mentioned. The muscle, in any case, which these languages have, derives from the fact that their original users control important commodities – wealth, dominance, learning – which others see as necessary for their own aspirations. The aphorism 'all roads lead to Rome' has linguistic meaning too.

It is sometimes said that if languages are all linguistically equal, they are not all sociolinguistically equal. In this vein, Joseph (1987: 25–39) pointed to the effects of print literacy and standardization in giving some forms of language and some languages an advantage over others, so that certain forms of language come to be seen as more important than others. But this should not be taken to mean that some languages are better placed in an absolute sense to serve a range of sociolinguistic functions (e.g., in formal speeches, writing, or television) than others. Every language has the potential to add to its characteristic vocabulary and ways of speaking if new roles become necessary. Some languages have a superior technical vocabulary to that of others in certain spheres. This is a difference in actuality rather than in potential.

Multilingualism: One Society, Many Languages

Many countries, especially in the West, attach special significance to one of their languages over others, adhering to an ethos of 'one state, one language.' Many of the states of Europe arose during a period of intense nationalism, with accompanying attempts to make national borders coterminous with language (and vice versa). The dominance of European powers in modern history has made this seem a desirable situation, if not an ideal one. The nonaligned sociolinguist instead points to the essentially multilingual nature of most human societies and to the fact that there are almost no countries in the world – even in western Europe – where everyone speaks, or identifies with, one language. In statistical terms, Grosjean (1982: vii) estimates that about half the world's population is bilingual. Romaine (1989: 8) points out further that there are about 30 times as many languages as there are countries. Even countries like France and England, which we are tempted to think of as monolingual, have, in fact, a vast array of languages within their borders. In France, for example, the following languages are still in use: French, Breton, Flemish (Vlaams), Occitan (Languedocien), Catalan (Catalan-Valencian-Balear), Basque (Navarro-Labourdin and Souletin varieties), Alsatian (a dialect of Allemanisch), and Corsican.

While multilingualism is not uncommon throughout the world, many schools have a policy that recognizes (and replicates) the hierarchy of relations within a territory and in the world as a whole. Only a small proportion of the 5000 or so languages of the world are used at the secondary level as media of instruction, and still fewer are used at the university level. Schools have often downplayed the value of the 'vernaculars' by minimizing their use in classrooms or recognizing them only as means of facilitating competence in the dominant language(s). Since the 1950s, and more especially since the 1970s, educationists have begun to recognize that multiculturalism is not a transient phenomenon. Sociolinguists are generally sympathetic to an approach that gives recognition to – and valorizes – as many of a society's languages as possible. This is in keeping with a holistic approach that is sensitive to the needs of children from different backgrounds ('bottom up') and not just the bureaucratic needs of the state ('top down').

Language Variation and Contact between Languages

These two branches of sociolinguistics ('language variation' and 'language contact') show above all others how much language and society influence each other. Some variation studies that are concerned with 'style, situation, and function' deal with the importance of contextual factors in determining different registers, styles, and genres. They also deal with the use of language in specific domains and functions, such as in advertising, religion, business, and e-mailing. The notion of a 'domain' is a particularly useful one. Fishman (1965) defined a domain as a sphere of activity arising from combination of specific times, settings, and role relationships, which results in a specific choice of language or style. The notion of 'register' is a linguistic counterpart of the sociological concept of domain. A register (Halliday *et al.*, 1964) refers to variation according to the context in which language is used. Relatively well-defined registers include the language of the law, the language of science, and the language of hip hop or jazz. Whereas register studies focus upon language use relatively independent of the users, social dialectology does the reverse. Dialects and social groups in the modern Labovian tradition are central to an understanding of

language variation and change. The emphasis in this tradition falls upon the finely nuanced differences within a language according to social groupings, based especially on class, gender, ethnicity, and region. The subfield of language contact stresses the reality that societies are rarely monolingual; languages exist amidst other languages. The idea of a pure and self-contained language is a poor, simplifying assumption, compared to the challenges of studying the ways in which speakers of different languages influence each other – how new languages (e.g., pidgins, creoles, 'New Englishes') may be borne out of struggle and how multilingualism is 'managed' by speakers at a microlevel and by societies at a macrolevel.

Social Interactions via Language

This section serves to introduce many of the 'Language in Society' entries covered in this encyclopedia (specifically excluding variation theory and language contact, which are covered elsewhere). The concept of communicative competence, as cited above, describes and accounts for the knowledge that people have that enables them to communicate appropriately in different social contexts. Speakers possess more than just grammatical knowledge. In a multilingual context, for example, interlocutors choose an appropriate code according to context. 'Context' includes the relative status of the interlocutors, the purpose of the communication, the respective rights and obligations associated with different language varieties, background knowledge, cultural rules of politeness, etc. This fine-tuning also applies to monolingual societies – this time relating to the choice of style to determine and reinforce the appropriate 'tenor' of the interaction. An example comes from the choice of an appropriate second-person pronoun in Hindi: *āp* for formal and respectful usage, *tum* for neutral usage, and *tū* for intimate or disrespectful usage. Such important determinants upon the use of language cannot be relegated to the study of 'performance' and hence be excluded from the domain of linguistics as a discipline (as it is within Chomskyan linguistics). Hymes popularized the field of the 'ethnography of speaking' within sociolinguistics, drawing upon anthropological traditions of studying speech in its social context and in terms of the value and meaning placed by individual speech communities upon specific speech events. Interactional sociolinguistics, associated with Hymes's occasional collaborator John Gumperz (e.g., 1982), is a subpart of the study of communicative competence that stresses the dialogic nature of speech. Like Bakhtin, the Russian linguist/critic who wrote in the 1920s to the 1940s, Gumperz insisted that linguistic signs are socially grounded, existing in context-bound encounters between individuals. Social and cultural forces, together with grammar and lexicon, constrain what can be said and how it can be said. An important part of this work concerned the identification of 'contextualization cues.' These are constellations of features of the verbal (e.g., vocabulary, prosody, syntactic choices) and nonverbal (e.g., gestures, facial expressions) configurations, which in the light of previous experience signal what kind of speech activity interlocutors consider themselves to be engaged in (e.g., banter, negotiating a loan, telling a story). The cues help establish social relations, set the frame for what will come next, fill in implicit information, and make inferences about the nature of the speech act. The allied field of 'ethnomethodology' (Garfinkel, 1967) in the social sciences, places such conversational and interactional speech analysis within a wider framework that encompasses all human action, which is seen as reflexively related to the occasions and settings within which it occurs. The focus falls on the perspective of participating members. For ethnomethodologists, the study of members' methods, including all types of practical reasoning and actions, is significant.

'Speech accommodation' is a particular perspective upon the communicative competence that fosters variation in speaker style. Giles and Powesland (1975) held that speakers attune their communicative style in relation to their interlocutor. The basic forms of accommodation are 'convergence' and 'divergence,' depending on the relative status of the speakers and the intended social relations. Bell's (1984) 'audience design' framework elaborated this scheme, taking into account not just the speaker, but the audience (authorized participants, overhearers, eavesdroppers, a displaced mass audience on radio, etc.)

The communicative competence of a speaker might involve proficiency in more than one language coexisting in a society. Whereas Chomskyan syntax focused on an ideal monolingual native speaker, scholars working in multilingual environments have called into question the idea of the native speaker. (As noted in the section above, "Language Is Not a 'Given,'" some scholars have also questioned the very assumption of a prior, well-defined heritable language.) Several commentators have pointed out that such definitions of a native speaker seem to be premised on the norms of monolingual societies, whereas in fact the world is largely multilingual (see Singh, 1998). In some multilingual societies, a child may be said to have several native languages, with the order of acquisition not being an indicator of ability. Multilingual speakers may switch languages according to situation in a way that monolingual speakers switch styles of the same language 'natively' (Scotton, 1985).

For many 'New English' speakers, monolingualism is the marked case, a special case outside of the multilingual prototype. Today's ideal speaker lives in a heterogeneous society (stratified along increasingly globalized lines) and has to negotiate interactions with different people representing all sorts of power and solidary positions on a regular basis. What is this ideal speaker a native speaker of, but a polyphony of codes/languages working cumulatively (and sometimes complementarily), rather than a single, first-learned code?

Studies of code-switching reinforce the notion that communicative competence goes beyond that of the monolingual's mastery of syntax. Accounts of the social and contextual motivations for code-switching have proven a necessary complement to purely structural approaches that seek to account for when in a sentence a speaker may (or may not) switch to another language (Myers-Scotton, 1993). Interaction between speakers, degrees of convergence and divergence, and intentions to alter the rights and obligations associated with one code rather than another have all been fruitfully employed to account for the facility that fluent bilinguals show in switching between languages. 'Crossing' is a particular kind of code-switching in which speakers use a variety that is not generally associated with their group (Rampton, 1995). It permits speakers from one group to overcome social boundaries and build links with members of what may be otherwise seen as an 'outgroup.' Crossing may have an accommodative and emblematic function, but it can also emphasize boundaries if the code used in the crossing reflects stereotypes about the outgroup's language use, rather than their actual practice. Crossing, which is done mainly by adolescents or postadolescents, is one way of calling into question set identities associated with older generations. The notion of identity is crucial in sociolinguistics, in which emphasis falls more on small, self-selected groups or larger groups tied to a regional identity, rather than on national identities.

A 'community of practice' is a collection of people who engage in a common activity on an ongoing basis. The value of the concept, introduced into sociolinguistics by Eckert and McConnell-Ginet (1992), lies in the identification of a social grouping not on the basis of shared abstract characteristics (class, ethnicity etc.) but on the basis of shared practice. The community of practice concept thus mediates between the vernacular (and its basis in early learned, localized forms of language) and official/bureaucratic/transactional language. A focus on the domains of usage and code choice pertaining to those domains necessitates an examination of language in its more bureaucratic modes. The field of language planning deals with the management of language resources of a state or other political entity. A formal language policy may be the outcome of language planning. Language policy may also refer to the norms of the speech community in its characteristic choices of language items or language varieties in relation to some conscious or unconscious ideology. Whereas one policy or another may have significant influence on the fate of a language, the field of language maintenance and shift shows that language legislation is seldom sufficient to halt the decline of a language. Factors associated with perceived economics and prestige amongst speakers and would-be speakers are equally important.

A fitting though sobering conclusion has to record sociolinguists' involvement in studies of language maintenance and shift in minority communities, and of language endangerment. It is predicted that the vast majority of the world's languages will face a struggle to survive in the present century (Krauss, 1992) as regionally and globally more powerful languages spread. The very cultural and linguistic diversity that sustained small and less powerful communities and that formed the core concerns of sociolinguistics and anthropology is under threat. Recording, cataloguing, archiving, and even teaching languages to communities who have few or no native speakers left have become vital concerns in linguistics.

Applications of Sociolinguistics

There are many practical outcomes of sociolinguistic research, especially in the field of language in education. Sociolinguists have contributed considerably to areas like the home language/school language interface, public debates about less-feted varieties like Ebonics (African American Vernacular English or Black English), an understanding of educational failure, enhancement of gender sensitivity in male-dominated classrooms, and so forth. Sociolinguists provide expert testimony in courtrooms based on their studies of discourse and accent patterns. They also contribute significantly to the growing attempts to save endangered languages and record their heritage, and they cooperate with educationists in government and nongovernment committees on language matters, especially those pertaining to minorities. Sociolinguists also contribute to cultural vitality by recording, describing, and popularizing rural speech and other varieties that are either denigrated or not always recognized as 'legitimate' language. This smooth and holistic interface between theory and application promises health and longevity to a young discipline.

Sociolect/Social Class

Those working in the field of variationist sociolinguistics generally look for some extralinguistic factor that may help to identify features of speech characteristic of groups of speakers. Although all speakers belong to multiple speech communities, four factors have proved the most durable: age, gender, ethnicity, and social class.

In principle, the easiest social factor to determine is age because at any given time an individual is a certain age, though some people may be reluctant to say what it is. Where precise information is not available, classification into broad categories can usually be estimated on the basis of appearance (Chambers, 1995). It is therefore not surprising that age regularly appears as an extralinguistic variable in sociolinguistic studies (e.g., Labov, 1963, 1966, 2002; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979; Milroy, 1980; Haeri, 1996; McCafferty, 2001).

However, as Eckert (1997) has pointed out, using age as an extralinguistic variable is not a simple matter. The obvious problem is that age is a continuous variable so that for purposes of correlation with linguistic features, speakers must be classified in age groups. Thus, any use of age as an extralinguistic variable requires a decision about how such age groups are to be identified and justified. Even a simple classification into adults and children is complex, not only because the age at which one can be counted as an adult is itself problematic but also because neither category will be homogeneous.

In comparison to age, gender, seen as a division into male and female, rather than sexual orientation, is relatively simple. Most people are accustomed to declaring their sex/gender in response to many kinds of enquiry and thus this information is usually available to the investigator. Gender is also generally fairly easy to determine on external criteria, although there may be ambiguous cases. Again, it is not surprising that gender is one of the factors frequently examined in sociolinguistic investigations (e.g., Fischer, 1958; Labov, 1966, 2002; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979; Milroy, 1980; Cheshire, 1982; Coupland, 1988; Haeri, 1996; Eckert, 2000; McCafferty, 2001).

Ethnicity is an even more problematic category than gender, not least because it can be determined with reference to a number of characteristics: race, nationality, religion. Any sociolinguistic investigation that includes ethnicity as an extralinguistic category will consequently need to specify clearly how membership in that category is to be established. However, in many situations the population is not ethnically diverse and thus such differences will not be salient in the community.

Social class is perhaps the category that has received the most regular attention from the earliest sociolinguistic studies (e.g., Fischer, 1958; Labov, 1966; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979), and it has continued to be examined in later studies (e.g., Coupland, 1988;

Those working in the field of variationist sociolinguistics generally look for some extralinguistic factor that may help to identify features of speech characteristic of groups of speakers. Although all speakers belong to multiple speech communities, four factors have proved the most durable: age, gender, ethnicity, and social class.

In principle, the easiest social factor to determine is age because at any given time an individual is a certain age, though some people may be reluctant to say what it is. Where precise information is not available, classification into broad categories can usually be estimated on the basis of appearance (Chambers, 1995). It is therefore not surprising that age regularly appears as an extralinguistic variable in sociolinguistic studies (e.g., Labov, 1963, 1966, 2002; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979; Milroy, 1980; Haeri, 1996; McCafferty, 2001).

However, as Eckert (1997) has pointed out, using age as an extralinguistic variable is not a simple matter. The obvious problem is that age is a continuous variable so that for purposes of correlation with linguistic features, speakers must be classified in age groups. Thus, any use of age as an extralinguistic variable requires a decision about how such age groups are to be identified and justified. Even a simple classification into adults and children is complex, not only because the age at which one can be counted as an adult is itself problematic but also because neither category will be homogeneous.

In comparison to age, gender, seen as a division into male and female, rather than sexual orientation, is relatively simple. Most people are accustomed to declaring their sex/gender in response to many kinds of enquiry and thus this information is usually available to the investigator. Gender is also generally fairly easy to determine on external criteria, although there may be ambiguous cases. Again, it is not surprising that gender is one of the factors frequently examined in sociolinguistic investigations (e.g., Fischer, 1958; Labov, 1966, 2002; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979; Milroy, 1980; Cheshire, 1982; Coupland, 1988; Haeri, 1996; Eckert, 2000; McCafferty, 2001).

Ethnicity is an even more problematic category than gender, not least because it can be determined with reference to a number of characteristics: race, nationality, religion. Any sociolinguistic investigation that includes ethnicity as an extralinguistic category will consequently need to specify clearly how membership in that category is to be established. However, in many situations the population is not ethnically diverse and thus such differences will not be salient in the community.

Social class is perhaps the category that has received the most regular attention from the earliest sociolinguistic studies (e.g., Fischer, 1958; Labov, 1966; Wolfram, 1969; Fasold, 1972; Trudgill, 1974; Macaulay, 1977; Feagin, 1979), and it has continued to be examined in later studies (e.g., Coupland, 1988;

Macaulay, 1991, 2005; Haeri, 1996; Foulkes and Docherty, 1999; Labov, 2001; McCafferty, 2001), though it has recently received less consistent attention as a key variable than in earlier studies. However, social class is a much more problematic category than the other three.

Despite receiving considerable attention in recent years by a range of scholars (e.g., see the references in Crompton *et al.*, 2000), social class remains a controversial subject with many conflicting views. From Lloyd Warner's pioneering studies (Warner, 1949) to Gilbert (2003) in the United States and accounts such as Reid (1989), Argyle (1994), and Cannadine (1998) in Britain, no clear method of identifying social membership has emerged. As Gilbert observes: "there is as much art as science in the study of social stratification" (Gilbert, 2003: 16). For sociolinguists, there is the added problem that the categories identified by sociologists or political scientists may not be the most useful for investigating language variation. Categories that are developed for studying national voting patterns or marketing strategies may not be the most appropriate for examining stratified uses of language in a smaller speech community.

There are two basic questions that are crucial in employing social class as an extralinguistic variable: (1) How many divisions are there within the category of social class? (2) How is membership in any of these divisions to be identified? In response to the first question some investigators (e.g., Fischer, 1958; Trudgill and Foxcroft, 1978; Macaulay, 1991; most contributors to Foulkes and Docherty, 1999; McCafferty, 2001) have treated social class as a dichotomous variable similar to gender with two polarized categories, usually working-class vs. middle-class, or blue-collar workers vs. white-collar workers (Chambers, 1995: 37). Other investigators (e.g., Labov, 1966; Wolfram, 1969; Fasold, 1972; Trudgill, 1974) have treated social class as a continuous variable similar to age and divided the continuum into categories on the basis of certain criteria. Still other investigators (e.g., Macaulay and Trevelyan, 1973; Feagin, 1979; Winford, 1993) have used a judgment sample based on a notion of several discrete social class divisions within the community. Feagin chose a sample that contrasted upper class with working class but also included distinctions according to age (adults over 65 vs. teenagers) and a rural/urban dimension. Winford chose a sample of Trinidadian males on the basis of occupation: middle-class (white-collar workers), upper working class (skilled and semi-skilled workers), and lower working class (unskilled workers and low-paid laborers). The method employed by Macaulay and Trevelyan will be presented below.

The answer to the second question about determining membership in a particular class will differ depending upon the way the sample is chosen. In a judgment sample, the membership in a certain category is determined in advance according the criteria employed (e.g., occupation, residence). In a random sample, the speakers will also be grouped according to similar criteria, but the linguistic data are sometimes used to refine this classification, as will be illustrated below.

The answer to both questions will also be affected by the degree to which social class is a salient category in the community. Social stratification may be nearly as universal as language but, like language, social stratification takes different forms in different societies. The extent to which social class differences are a common feature of public discourse will affect the ways in which membership in a particular category can be identified. Cannadine (1998) and Milroy (2004) have pointed out that social class is a much more salient notion in Britain than in the United States.

Argyle (1994) points out that with regard to the situation in Britain: "Part of the evidence that there *is* a class system is that about 95 per cent of the population think there is, and can say which class they belong to themselves" (Argyle, 1994: 3). Given the desire to use social class as an extralinguistic variable, it is necessary to have some basis on which to choose the sample. Labov (1966) was able to make use of an earlier survey that had been designed by the New York School of Social Work for the Mobilization for Youth survey with a team of 40 interviewers. Probably no other sociolinguist has had such a large randomly chosen sample to work with in a single community.

Labov made use of a 10-point socioeconomic class index developed for the Mobilization for Youth survey by John Michael based on measures of occupation, education, and income. Labov points out that Michael gave "considerable attention to the problem of dividing the continuum of social class" (Labov, 1966: 216), and this was a problem for Labov, too. Labov did not only correlate use of the linguistic variables with speakers from each of the ten points on the scale. Instead, he usually grouped the speakers into three or four social class groups and illustrated the difference this can make (Labov, 1966: 220–248). The most interesting of these is the difference between Labov's figure for the class stratification of the variable (r) (1966: 22, Figure 1) and another figure (1966: 240, Figure 11) for the same variable. In the first, Labov has three groups: 0–2 (the lowest group), 3–5 (the middle group), and 6–9 (the highest group). The three groups show the same stylistic stratification.

In the other figure (which is the most frequently cited example of hypercorrection), there are six groups (0, 1, 2–3, 4–5, 6–8, and 9). The separation of 9 from 6–8 shows that the speakers in the latter group use more /r/ in reading aloud word lists and sets of minimal pairs than the speakers in the highest group. This difference was concealed by the grouping used in the first figure. The example illustrates one of the problems with 'dividing the continuum of social class.' There is clearly a linguistic justification for the grouping in the latter figure, but is there other evidence that the speakers in, for example, category 8 belong with those in categories 6 and 7 rather than with those in category 9? For the (dh) variable (i.e., the use of a stop or an affricate instead of a fricative in words such as *this* and *then*), Labov divides the continuum into three groups: 0–4, 5–6, 7–9. This produces a regular stylistic pattern in a third figure (Labov, 1966: 246, Figure 15). However, from the list of speakers who used either stops or affricates (Labov, 1966: 259, Table 5), there is an argument for dividing the speakers into only two groups 0–4 and 5–9. In the first group, 14 of the 46 speakers (30%) used stops or affricates, in contrast to the second group, in which only 2 of the 35 speakers (6%) used any stops or affricates, a highly significant difference. Later, Labov (1966: 274, Figure 2) shows that educational level accounts for this dichotomy: speakers with less than a 10th-grade education have a much higher frequency of stops and afficates. However, rather than employ the division into two social classes, Labov goes on to develop a four-point social class scale on the basis of education and employment (Labov, 1966: 278) that shows a more regular distribution of the speakers from the lowest social class to the highest in their use of (dh). However, in a reanalysis of Labov's data, Horvath (1985: 64–65) showed that gender was also a powerful determinant of (dh) and better helped to explain the deviant case of Nathan B. (Labov, 1966: 249–253). Chambers (1995: 55–57) points out that the use of fewer non-standard variants of (dh) is an important feature of upwardly mobile speakers, suggesting that this variable is salient for such speakers.

Labov thus presents various arguments for different social class groupings of the speakers, but his questionnaire does not include any question for the speakers about their own view of their class affiliation. Either he did not think it was appropriate, or perhaps he thought his respondents might have difficulty in answering it. However, their answers might have helped to choose between the various groupings rather than depending upon the linguistic analysis to justify the categories. Plausible criteria for identifying social class categories and membership are crucial when social class is employed as one of the extralinguistic variables.

Labov (2001) followed a similar strategy in his later Philadelphia Neighborhood Study. On the basis of education, occupation, and residence value, he developed a 16-point scale which he then divided into six social classes. Labov used regression analysis to tease out the different effects of occupation, education, and residence value on the use of the variables (2001: 183–186). He concluded that occupation was the most important factor (Labov, 2001: 185). The other factors are perhaps more relevant to notions of social prestige in general than to categories of social stratification. The differences in occupation, however, do not provide a clear answer to the question of how many social classes there are.

It is hard to be sure from Labov's charts (2001: 168–171), but there would appear to be a major difference between his first three groups (the working class groups) and the other three (the middle class and upper class groups). In terms of social class differences, a two-way division would probably have provided clear evidence of the difference between the two. Would this have been a more accurate picture of social class differences in speech than the one that Labov presents? In the absence of any corroborating evidence, it is impossible to tell, but the question is central to an understanding of the relationship between language variation and social class.

Trudgill (1974) also selected a quasi-random sample, from the local register of electors from four of Norwich's electoral wards. Trudgill then developed a social class index on the basis of six separate indicators: occupation, father's occupation, income, education, locality, and housing. One problem with this approach is that each of the indicators is taken to have an equal effect on social class, and that assumption may not be justified (Macaulay, 1976: 185). Like Labov, Trudgill then, on the basis of linguistic data, grouped the scores on the 30-point range into groups that he labeled Middle middle-class, Lower middle-class, Upper working-class, Middle working-class, and Lower working-class. Trudgill was able to show fine stratification in these five categories, but a skeptic looking at his results might wonder whether the separation of the working-class speakers into three categories is justified. Like Labov, Trudgill did not ask his speakers about social class or where they would put themselves.

Labov's and Trudgill's methods are worth examining closely because they are scrupulously honest and make it quite clear how they arrived at their categories. However, they also illustrate the difficulties that sociolinguists face in employing categories such as social class. It is not enough to choose a way of

dividing up the sample into discrete groups; there has to be some reason to believe that these groups correspond to actual social divisions. Those who have not employed multiple indices have usually taken occupation as the main criterion for membership of a particular social class (e.g., Macaulay, 1977; Coupland, 1988; McCafferty, 2001), but some investigators have used place of residence (e.g., Stuart-Smith, 1999). Such criteria, however, are no guarantee that the resulting categories correspond to actual social classes.

When I was planning my work in Glasgow (Macaulay and Trevelyan, 1973; Macaulay, 1977), the most recent work on Scottish society was Kellas (1968) in which it was suggested that there were three major social class divisions in Scotland, based on occupation. In adopting this classification, I modified it, splitting Kellas's middle category by separating manual workers from non-manual. This gave four social class groups: I, IIa, IIb, III. The Registrar-General's list of occupations provided a guide to membership in each of these categories. I used these categories to identify a judgment sample of speakers, balanced for gender and age (10-year-olds, 15-year-olds, and adults), and the use of five linguistic variables was correlated with these categories. On the basis of the results of the analysis, it became obvious that there were no significant differences between groups IIb and III. In other words, the difference between manual (IIb and III) and non-manual (IIa) workers proved important. Thus, like Labov and Trudgill, I modified my classification on the basis of the linguistic data.

As part of the interview, I had included questions for the adult speakers about the number of social class categories in the city and where they would place themselves. Their responses were consistent with the notion of a three-part division (Macaulay, 1976) that matched the results of the linguistic analysis. However, it also appeared that there was no clear label for those who fell between the polarized groups of working-class and middle-class. As one woman put it:

> Well I wouldn't call myself middle-class but on the other hand I would call myself middling. In other words, I'm not up there and I'm not down there. I just reckon I'm pretty average. [Macaulay, 1977: 63]

This speaker sees the middle-class as being 'up there' and the working-class as being 'down there,' but she does not have a simple label for people like herself who are 'pretty average.' This comment illustrates the danger of taking a label such as 'middle-class' literally. The Class I speakers also resisted the suggestion that they were 'upper class', although they admitted that they belonged to the upper stratum of Glasgow society.

Responses such as this one and others collected in the Glasgow survey (Macaulay, 1976) show that even when social class divisions are salient in the society, there may not be an adequate public language in which to label the differences. Nevertheless, the kind of subjective opinions elicited in the Glasgow survey can be useful in identifying how the speakers themselves perceive the critical social class divisions in a society. Perhaps investigators carrying out large-scale sociolinguistic surveys could incorporate some of the methods of perceptual dialectology (Preston, 2002).

There is, however, little evidence that many investigators are planning large-scale surveys of specific communities in which social class differences might be significant in accounting for language variation. A preoccupation with linguistic change has perhaps deflected attention from wider goals. This is unfortunate because social class differences are obviously important in predicting educational achievement, and language skills are fundamental to success in the school system. More attention by sociolinguists to aspects of language variation other than pronunciation might be helpful in educational planning.

Given the complexity of dealing with social class, some investigators have followed the example of the Milroys (Milroy and Milroy, 1978; Milroy, 1980) in using social networks as the basis for examining language variation. Social networks are "personal communities which provide a meaningful framework for solving the problems of daily life" (Milroy, 2001: 550). A network approach "provides a set of procedures for studying small groups where speakers are not discriminable in terms of any kind of social class index" (Milroy, 2001: 556).

A similar kind of approach is to examine a community of practice. "A community of practice is an aggregate of people who come together around mutual engagement in an endeavor" (Eckert and McConnell-Ginet, 1992). Eckert (2000) demonstrates the value of this approach in her study of high school students in Detroit. The difference between a social network and a community of practice is not simply one of size, though networks have the potentiality to be much larger than communities of practice. One important difference is that an individual 'may belong to or participate in a number of different communities of practice' (Meyerhoff, 2001: 531), while individuals will rarely belong to numerous social networks.

Social networks and communities of practice provide an alternative basis for approaching language variation, but they do not replace the larger notions of age, gender, ethnicity, and social class, because individuals will still have these characteristics.

However, all four categories interact in complex ways (Eckert, 2003; Macaulay, 2005) and thus generalizations about the effect of one factor may be misleading without taking the others into consideration. For this reason, claims about social class differences in language should always be carefully examined for possible sources of bias and the empirical basis for the claims. For example, it is not always made clear that Basil Bernstein's wide-ranging claims about social class differences in Britain (Bernstein, 1962) were based on small samples of speech from ten middle-class boys and fourteen working-class boys, aged between 15 and 18, recorded under inadequate conditions of control (Macaulay, 2005).

Despite the problems, social class has been shown to be related to variation in many aspects of language. It is not possible here to review all the work that has been done in many parts of the world, but some illustrative examples will suggest the range of investigation. The majority of studies have dealt with phonological variables. Differences in vowel quality have been found to correlate with social class differences in a number of studies (e.g., Labov, 1966, 2001; Trudgill, 1974; Macaulay, 1977, 1991; McCafferty, 2001), but interestingly more robust correlations have often been found for consonants (e.g., Labov, 1966; Wolfram, 1969; Trudgill, 1974; Macaulay, 1977; Coupland, 1988; Milroy *et al.,* 1994; McCafferty, 2001). This may be because consonantal variables are often stable sociolinguistic features, though the recent spread of glottal stops in Britain is an obvious exception. Social class differences in intonation have not been investigated systematically, but that may change with developments in instrumental techniques of measurement. Stuart-Smith (1999) has examined social class differences in voice quality in Glasgow. She found that working-class Glaswegian voice quality had more open jaw, raised and backed tongue body with possible retracted tongue root, and whispery voice. She observes that middle-class Glaswegian voice quality "is best described in terms of the *absence* of WC traits" (Stuart-Smith, 1999: 215).

In morphology, social class differences have been found in tense marking (e.g., Wolfram, 1969; Fasold, 1972; Feagin, 1969; Macaulay, 1991). Social class differences in forms of negation have also been found in widely different communities (e.g., Wolfram, 1969; Feagin, 1979; Macaulay, 1991). With regard to modality, Feagin (1979) showed that there were social class differences in the use of double modals (e.g., *she might could be a big help to you*) and the quasi-modal *liketa* (e.g., *she liketa had a heart attack!*) in Anniston, Alabama. Thibault (1991) identified social class differences in the use of *devoir* as a modal in Montreal. Winford (1993) found social class differences in the use of perfect *have* in Trinidadian English.

A small-scale study showed social class differences in the use relative pronouns in Ayr (Macaulay, 1991) with the middle-class speakers much more likely to use *wh*-relatives. In a longitudinal study of Montreal French, Blondeau (2001) found that simple non-clitic pronouns (e.g., *nous* vs. *nous autres*) were more common in the upper levels of the social scale in Montreal. In another Montreal study, Dubois (1992) described social class differences in the use of extension particles with the professional class more likely to use forms such as *et cetera* while the working-class speakers preferred forms such as *patati patata*. Macaulay (2001) showed that in Ayr and Glasgow, working-class speakers used significantly fewer derived adverbs and intensifiers such as *very* than the middle-class speakers.

In a study of discourse variation in a sample of Glasgow adolescents and adults, Macaulay (2005) found that three-quarters of the 32 discourse features examined showed no social class differences. In addition to the differences in adverbs and relative pronouns mentioned above, the working-class speakers used more modal auxiliaries and more dislocated syntax, such as clefting or right and left dislocation (e.g., *Mr. Patterson he was a gentleman*). The middle-class speakers used more passives and more evaluative adjectives, as well as the hedge *sort of*. The lack of more significant differences led to the conclusion:

> Despite important differences in education, income, and place of residence, the Glasgow speakers use language for the most part in very similar ways. (Macaulay, 2005: 157)

This point perhaps needs emphasizing in any account of language variation. While age, gender, ethnic, and social class differences in language are of interest and may often be socially important, these differences are small in comparison with what the speakers have in common with each other.

Sociolinguistic Crossing

P Auer, Universität Freiburg, Freiburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Research on code-switching (*see* **Code Switching**) tends to start from the assumption that the languages used in a bilingual encounter are, matters of bilingual competence aside, equally accessible and available to all participants, and that the participants belong to one bilingual community in which a common repertoire of linguistic resources is shared. Often, the languages of this repertoire are organized along such dimensions as we-code/they-code, minority/majority language or standard/nonstandard. This assumption is justified in many cases, while it amounts to a considerable idealization of the facts in others. In yet other cases, code-switching has remained outside the scope of bilingual studies for the very reason that in a most blatant way, one of the languages or varieties used in the bilingual encounter does not belong to the speaker, i.e., its use implies a transgression, an act of trespassing into the linguistic territory of another group of speakers who have privileged or sole access to it, by a speaker who is not an accepted member of that group. Such cases of code-switching will be called sociolinguistic crossing in the present article. Crossing then always implies three parties: a speaker who crosses, the owners of the language or variety into which the crossing is done, and a recipient in the bilingual encounter in which the crossing occurs. The recipient may of course be one of the owners, but the owners may also be absent or mere bystanders.

It is obvious that the interpretation of an act of code-switching as a transgression is open to negotiation and may not be shared by all participants involved. For instance, a speaker may not intend to cross into linguistic territory *extra muros* believing that he or she is part of the group who owns the variety switched into; he or she may on the contrary believe that he or she crosses into another variety while the others do not see themselves as distinct from the speaker's social group; and the recipient may side with the speaker or with the owner in his or her interpretation. But in all cases, sociolinguistic crossing raises questions of boundary-marking, of maintaining or contesting, building or tearing down social borders. It makes these matters relevant to the interaction, although group boundaries are not usually a topic of talk in the situation.

Greatly simplifying, crossing may, as an act of alterity, either be antagonistic, i.e., aimed at maintaining or reinforcing group boundaries, or it may, as an act of identity, be accommodating, i.e., aimed at camouflaging or making irrelevant group boundaries, or even establishing new social categories and ideological alliances. However, as we shall see, the interpretation of crossing is often a complex issue in which the situational context plays a decisive role.

In addition to the allocation of the role of the code-switching speaker, the recipient and the owner of the crossed-into language, and to their interpretation of the code-switching as antagonistic or accommodating, the linguistic form of the code-switch needs to be taken into account. It is important to distinguish between straight crossings in which the variety or language crossed into is more or less identical to the one used in the owning group, and crossings in which the code-switching speaker stylizes a typical speaker of the owning group. Sometimes, he or she will then use a mock form of that variety or language. Some examples may be useful to show the amount of variability in crossing, and the linguistic activities on which or for which it is employed.

First of all, sociolinguistic crossing may be involved in any quotation of another voice. The current speaker then animates another past or future, factual or fictitious, generic or individualized speaker, giving him or her a typified or even stereotypical representation through language choice, accent, prosody, or any kind of social-communicative style that is not associated with the teller's own social persona. Such cases of reported speech always involve double-voicing, i.e., an overlay of the reported voice and the reporter's, as has been shown by many studies in the tradition of Bakhtin (1973 [1981])/Voloshinov (1929 [1993]) (cf., e.g., Günthner, 1999, in press). For instance, Keim (2002) discusses an example in which a Turkish-German bilingual girl brought up and living in Germany animates her mother's voice in *Gastarbeiterdeutsch* (a simplified variety of German which her mother, a first generation work migrant, speaks). For the daughter, who is a fluent speaker of colloquial German, this transgression into a variety which does not belong to her but typifies another social group (that of first generation *Gastarbeiter*), is clearly antagonistic: she uses language in order to erect a social boundary between her mother and herself, which, in the context of the interaction at hand, serves to criticize the mother's point of view in an argument. This point of view is discredited by the very fact of being associated with the social group indexed by the variety switched into.

Reported speech, although often involving sociolinguistic crossing, is not where the term has originated from, however. Rather, it was introduced by Rampton (1995, 1998) in his study on the use of

London Jamaican Creole and other immigrant varieties in the UK (Punjabi and Indian English) by white English adolescents in London, which in turn built on previous sociological work by Hewitt (1986). Rampton observed crossing not in interactions between entitled and nonentitled users of the codes, but rather, in intragroup situations where the crossers were among themselves. (Hewitt, 1986 in fact reports sanctions by Creole speakers when whites used it, which explains this finding.) He found this bilingual practice to occur in what he calls liminal situations, i.e., "at the boundaries of interactional enclosures, in the vicinity of delicts and transgressions, in self-talk and response cries, in games, cross-sex interaction and in the context of performing art. Adolescents used language to cross ethnic boundaries in moments when the constraints of everyday social order were relaxed" (Rampton, 1995: 281). The interpretation of crossing is, according to Rampton, more complex than that of in-group code-switching: "Recipients have to run through a much more extensive set of possible inferences in order to make sense of an utterance, and [. . .] it is this often unfinished process that generates the symbolic resonance around an utterance" (Rampton, 1995: 278). Crossing is particularly rich in inferences; this is so, not in the least, because there are no established interpretational routines involved, and because crossing calls into question some very fundamental assumptions of everyday language-based categorization work.

Its exact meaning is difficult to pinpoint and requires a close look at its contextual embedding. Accommodating tendencies in which the crossers attempt to borrow some of the prestige that the creole doubtlessly has on a nonofficial language market in which street-wiseness, virility, and verbal virtuosity are highly appreciated (cf. Sebba and Tate, 2002) do not necessarily imply a wish to identify with the social-ethnic category of the West Indians in Great Britain. A similar ambiguity was observed by Cutler (1999) in a study on crossing into African-American English by white Anglo-American youngsters. On a wider scale, the use of American English by British English pop singers (as described by Trudgill, 1983) can also count as an instance of accommodating crossing. It seems that some prestigious symbolic resources tend to dissociate from the social group who originally owned them (perhaps against their will) and to become more widely available as an index to those moral values and ideologies that have come to be associated with the owning group. The worldwide borrowing of cultural resources from African-American culture (such as hip-hop music) are a case in point. However, crossing is also observed in sociolinguistic contexts in which the crossed-into variety has no prestige (not even a covert one). For instance, code-switching into Hindi is part of a funny style used among Fijians, with secondary functions of boundary marking against the Hindi minority (Siegel, 1995).

Although the use of stylized and highly exaggerated varieties seems to be a straightforward case of antagonistic crossing (cf. Hill, 1995), there can be a large amount of interpretational ambiguity in parody as well. In addition, everyday crossing of this kind is usually mediated by models made popular through the mass media such as TV shows, movies, or advertisements (cf. Sebba, in press, on the role of Ali G. in the UK). As an example, consider the use of a stylized variety of ethnolectal German. This variety, which is associated with Turkish and other 2nd generation immigrants in Germany (other than the *Gastarbeiterdeutsch* referred to above, which is the result of a fossilized process of spontaneous acquisition in first-generation immigrants), has become popular among German adolescents of a nonmigrant background through being used in the mass media. This secondary ethnolect in turn is copied and transformed by the monolingual German adolescents (thereby becoming a tertiary ethnolect), who themselves may have no direct contacts with the social group with which the primary ethnolect is associated (cf. Androutsopoulos, 2001; Auer, 2003a). As Deppermann (in press) shows, crossing into a stylized ethnolect of German can serve to stylize another social group (that of a particular type of immigrant youngster) as a relevant alterity, which provides an oppositional display of one's own social identity; more often, however, it indexes media competence and access to a code that is as fascinating as its primary owners are despised.

Questions of ownership of a variety may be an issue that makes the interpretation of a style shift as antagonistic crossing difficult as well, as Coupland (in press) shows in an analysis of style shifting in the Welsh Labour politician Aneurin Bevan. Although Bevin, in his political speeches, often uses standard or exaggerated RP pronunciation in order to caricature his political enemies – without quoting them – and 'Valleys' Welsh English features in order to align with his political supporters (the workers), there is by no means a one-to-one relationship between stylistic choices and political assessments. Bevin does not consistently treat standard English/exaggerated RP as a variety not owned by himself, but uses it as a voice of authority and honesty as well, which is owned by him as a member of the political elite just as the accent of his Welsh background is.

In a particularly obvious way, the dissociation of symbolic resources and their meanings from the social group which can be called their owners applies to crossing into school languages by the learners, particularly for ludic functions. For instance, the use of a song-line from a German pop song by Turkish-Danish bilingual adolescents (Jørgensen, 2005) or the use of German fragments by British pupils in London (Rampton, 1999) is part of a widespread usage of foreign languages for playful reasons in adolescents' social styles. It is only marginally related to social boundaries and their transgression; here, we reach the limits of sociolinguistic crossing in the sense of the definition given above.

Finally, it should be clear that the use of a particular code by certain speakers that comes as a surprise **to the analyst** does not *eo ipso* qualify as sociolinguistic crossing; for instance, the unexpected use of a minority language by speakers of the majority (such as Turkish by (ethnic) Germans – cf. Auer, 2003b; Dirim and Auer, 2004) is part of the emerging multilingual youth styles that are typical of some multiethnic metropolitan spaces in Europe. As a rule, though, these social-communicative styles do not address issues of ethnic boundary-making but rather index a social milieu in which certain languages are an integral part of everyday life.

Sociolinguistics and Political Economy

M Bucholtz, University of California, Santa Barbara, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Since the beginnings of sociolinguistics, it has been well established that language and economic structures are interrelated. Other social sciences concerned with political economy have been largely dismissive of language, viewing it as an entirely symbolic rather than material phenomenon. By contrast, sociolinguists – including both those who describe and those who critique capitalist systems – have repeatedly and conclusively demonstrated that language is intimately tied to speakers' material economic position.

The earliest work examining this relationship concentrated on the linguistic dimensions of social class, particularly the social and economic reflexes of the standard and the vernacular forms of a language. The robust correlations that variationist sociolinguists found between socioeconomic status and language use were cited as powerful evidence of the social organization of linguistic variation. Variationist sociolinguistics was also instrumental in redirecting scholarship on speakers living in poverty from a framework centering on language deficiencies to one focused on linguistic difference.

Whereas the first studies of language and social class were largely framed within a structural-functionalist paradigm in which social classes orient to the same social norms, and in which class organization is consensual, scholars informed by Marxist theory have argued that a conflict-based model of class would improve the fit between sociolinguistic findings and the social theories used to account for them, insofar as language is used not only in parallel fashion across classes but also to carve out social differences between classes. The difficulties of objectively determining class led other researchers to focus on social networks, in which occupation figured heavily, as a way of arriving at locally meaningful social groupings for linguistic analysis.

Social class has been at the center of a longstanding debate in sociolinguistics: how to account for the widespread pattern in which women are frequently found to surpass men in the use of standard variables. One early explanation for this pattern was that women, lacking equal access to real-world power, use language as a symbolic resource to claim social prestige by projecting through their speech a class position above their actual material circumstances. A revised version of this argument posits that women more than men are socially evaluated not on their accomplishments but on their personhood, and that language is a crucial component of self-presentation. This account allows for the possibility (which has been empirically demonstrated in variationist-sociolinguistic research) that some female speakers might seek to project a working-class rather than middle-class persona and hence will outpace their male counterparts in the use of vernacular rather than standard variables.

This analysis of the semiotic power of language relies heavily on the work of Pierre Bourdieu, a central theorist in sociolinguistic discussions of political economy. For Bourdieu, language is a form of capital, a term that for him includes not only economic power but also social, cultural, and symbolic power. Bourdieu argues that when a linguistic market is constituted in a society, the distribution of linguistic capital – that is, the form of the language imbued with the most power within the market – is uneven across speakers. The economic analogy is not wholly metaphorical, for Bourdieu notes that power in the linguistic marketplace tends to extend to power in the economic marketplace as well. However, language can function as a primarily symbolic form of capital that enables speakers to accrue local prestige, such as popularity among high school students in the United States, although even in this situation speakers' choice of linguistic variables tends to correlate with their orientation to socioeconomically divergent pathways after high school: jobs versus college.

The relationship between language and work, which has long informed variationist socioinguistic research, has also been explored within other paradigms. Ethnographic sociolinguists have documented the ways in which opportunities in the labor market are tied to language, demonstrating not only that lack of access to linguistic capital prevents economic mobility, but also that even within a limited field of options speakers may make agentive and strategic linguistic choices to promote their own social goals, whether these involve economic advancement or participation within a local linguistic and economic market. Although scholarship on standardization, language shift and loss, and the international spread of English has shown that broad political-economic forces such as nationalism, colonialism, industrialization, and globalization have dramatic and often catastrophic consequences for language, such research also demonstrates that these forces cannot fully determine speakers' linguistic practices.

In contrast to much of the work on language and economic systems discussed above, which considers the linguistic consequences of broad economic structures and processes, research within discourse analysis

considers the details of language use within specific economic contexts. A body of literature in several subfields has examined a wealth of issues regarding language in the workplace. Interactional sociolinguists, concerned with how cultural differences in interactional style may lead to misunderstandings and conflicts between interlocutors in culturally diverse work settings, seek to document the pragmatics of talk among coworkers and between service providers and customers or clients. Scholars working in the traditions of interactional sociolinguistics, conversation analysis, critical discourse analysis, and other approaches have also given extensive attention to language use in institutional settings such as medical contexts, the legal system, the educational system, and the media, in which issues of power and economic access are centrally relevant. And as both multilingual linguistic competence and friendly, facilitative interactional practices have emerged as marketable skills within the postindustrial service economy, scholars have begun to document the ways in which the linguistic abilities of a diverse workforce come to be shaped to the needs of late capitalism.

Although socioeconomic structures and institutional contexts have been the aspects of economic systems most central to sociolinguistic research, another crucial element of economic processes, consumption, has begun to gain ground. The relationship between language and consumer culture has been of deep interest particularly within critical discourse analysis and other politically oriented sociolinguistic frameworks. Focusing on advertising discourse, popular media textual products such as mass-market fiction and television shows, and other commodified forms of discourse, this body of work offers a critical perspective on how members of the public are transformed into consumers. However, research is still greatly needed on how people both at the center and on the periphery of consumer culture use language to make sense of such texts and of other aspects of consumption in their daily lives.

Related to this issue is the phenomenon of commodified language – language that functions not only as labor but as a product for consumption. Such commodification is most vividly seen in the appropriation of symbolically laden languages and dialects in advertising, mass media, and popular culture to enhance corporate profits, but it is also evident in the promotion of talk as a valued object in its own right in all aspects of late capitalist society, as seen in the marketing of verbal intimacy from psychotherapy to phone sex to coffeehouse conversations.

Many other arenas of language and political economy are only recently being explored by sociolinguists, particularly within newly industrializing societies and those most dramatically reshaped by globalization. Indeed, it is not an overstatement to assert that every aspect of sociolinguistics touches on political-economic issues. As those working in the many branches of the field continue to pursue their diverse research agendas, scholarship will benefit greatly from deeper and more extensive attention to this powerful and pervasive aspect of sociolinguistic life.

Sociophonetics, as is evident from its morphology, describes work at the intersection of sociolinguistics and phonetics.

The term has had its widest currency among phoneticians, referring especially to descriptive accounts of phonetic and phonological variation in particular dialects, speech styles, or speaker groups. The results of such investigations are often used to address issues in phonetic and/or phonological theory. One such issue is the relationship between phonetics and phonology (e.g., Ohala, 1990), although many sociophoneticians appear to make no distinction between them, using 'phonetics' and 'phonology' interchangeably. Sociophonetics is also used to refer to phonetically oriented research in variationist sociolinguistics. Such work again focuses on the interrelationships between phonetic/phonological form and social factors such as speaking style and the background of the speaker, but with a particular interest in explaining the origins and transmission of linguistic change.

Among the first to define her work as 'sociophonetic' was Deshaies-Lafontaine (1974), in a study of Canadian French. Dressler and Wodak (1982) used the near-synonymous label 'sociophonological' for their study of Vienna German. Although the

Sociophonetics, as is evident from its morphology, describes work at the intersection of sociolinguistics and phonetics.

The term has had its widest currency among phoneticians, referring especially to descriptive accounts of phonetic and phonological variation in particular dialects, speech styles, or speaker groups. The results of such investigations are often used to address issues in phonetic and/or phonological theory. One such issue is the relationship between phonetics and phonology (e.g., Ohala, 1990), although many sociophoneticians appear to make no distinction between them, using 'phonetics' and 'phonology' interchangeably. Sociophonetics is also used to refer to phonetically oriented research in variationist sociolinguistics. Such work again focuses on the interrelationships between phonetic/phonological form and social factors such as speaking style and the background of the speaker, but with a particular interest in explaining the origins and transmission of linguistic change.

Among the first to define her work as 'sociophonetic' was Deshaies-Lafontaine (1974), in a study of Canadian French. Dressler and Wodak (1982) used the near-synonymous label 'sociophonological' for their study of Vienna German. Although the

term therefore has a reasonable time depth, the field has expanded rapidly since the mid 1990s. Sociophonetics is now an eclectic field with an expanding agenda. It is furthermore emerging as a research area in its own right, instead of being viewed as a component of other, more established traditions. Today's sociophoneticians are concerned not only with aspects of speech production, but also with the effects of variation on speech perception; the implications of variation for theories of language change, the lexicon, phonology, and speech production and perception; how variation impacts the process of language acquisition; and the value of understanding variation for a range of applied areas.

This review illustrates these areas with reference to key works. It should be borne in mind, however, that the authors cited may not themselves have used the term 'sociophonetic' to describe their research.

Speech Production

The majority of sociophonetic work has been concerned with social, regional, and stylistic variation in speech production. Variationist sociolinguistics in particular has yielded a wealth of information to show that variation in speech production is systematically influenced by a range of factors. These include aspects of speakers' social background such as their age, gender, ethnicity, and socio-economic status (e.g., Labov, 1966, 1994–2001). Further influence may come from the groups and social networks with which speakers are affiliated (e.g., Milroy, 1987; Eckert, 2000).

Interest in regional variation predates modern linguistics. Systematic large-scale surveys of many languages have been carried out since Georg Wenker used a postal questionnaire to investigate the German dialect forms used by schoolchildren in 1876. Recent surveys have used innovative methods such as telephone interviewing to gain rapid access to large samples of informants (e.g., Labov's TELSUR project). More work has been carried out on English than any other language (but see e.g., Verstraeten and Van de Velde, 2001; Kissine *et al.*, 2003 on Dutch; Sankoff *et al.*, 2001 on Canadian French). Wells (1982) provided a comprehensive account of regional variation in English accents, while Foulkes and Docherty (1999) contained several detailed studies on varieties in the British Isles.

It has also been demonstrated that phonetic and phonological form may be influenced by many dimensions of the context of interaction. These include the style or register of speech, the topic of discussion, and the addressee. Style-shifting (sometimes called phonostylistics) was summarized by Schilling-Estes (2002). A common finding is that more formal registers tend to elicit more standard spoken forms. In a slightly different vein, Lindblom (1990) hypothesized that speakers adjust their speech along a 'hyper-hypo' continuum, in accordance with the perceived interactional needs of the interlocutor. More elaborated (hyper) articulations are used if the context demands listener-oriented speech, such as giving clear instructions. On the other hand, articulatory control in interactions such as narratives may be more speaker-oriented, permitting a greater degree of underarticulation (hypo-speech).

Variation in speech may contribute to expressing solidarity with, or distance from, an interlocutor. An example was provided by Trudgill (1986: 8), who monitored his own speech during fieldwork in Norwich, England. He found his use of glottal stops for /t/ correlated with that of his interviewees. Recent phonetic studies further reveal that interlocutors exert very fine control over phonetic parameters in order to structure discourse, for example to control turn-taking (e.g., Local, 2003). It has also been shown that adults modify their speech when addressing children, including the use of higher fundamental frequency (F0) and a wider F0 range. Sociolinguistic variables may appear with different distributions relative to patterns in inter-adult speech, and may be affected by the age and gender of the child (Foulkes *et al.*, 2005). Bilingual interaction displays a unique range of addressee effects, in that patterns of interference between languages depend upon the "language mode" being used (Grosjean, 1998). In some circumstances a bilingual is likely to use just one language, such as speaking to a monolingual. In a monolingual mode, any interference between the speaker's two languages is minimal. However, in conversation with other bilinguals code-switching often emerges. That is, speakers engage in a bilingual mode where both languages are used and structures from one language may well be transposed onto the other. The phonetics and phonology of bilingualism remain, however, under-researched relative to other linguistic features (but see e.g., Khattab, 2002). Another area which has only just begun to attract attention is how variation is learned in the course of language acquisition. The available evidence (summarized by Roberts, 2002) suggests that children acquire knowledge of sociolinguistic variation from the earliest stages.

Speech production research has been based mainly on auditory and acoustic (spectrographic) analysis of segmental properties. Sociolinguists in particular have relied on acoustic analysis to study vowels, especially formant analysis of stressed monophthongs (e.g., Labov, 1994–2001). Acoustic analysis has been extended to other aspects of vocalic quality such as

duration (e.g., Scobbie *et al.*, 1999) and formant transition rate (e.g., Thomas, 2000), and to consonantal variables (e.g., Docherty and Foulkes, 1999; Kissine *et al.*, 2003). Work on suprasegmental features is increasing as well. These include regional and social variability in intonation (e.g., Britain, 1992), voice quality/vocal setting (e.g., Henton and Bladon, 1988; Stuart-Smith, 1999), and rhythm (e.g., Low *et al.*, 2000). Further advances have been made as a consequence of technical developments in recording and analysis methods. Nolan and Kerswill (1990), for example, were innovative in employing electropalatography to analyze variation in connected speech processes. Other techniques such as ultrasound, laryngography, electromyography (EMG), and electromagnetic articulography (EMA) promise much for the future of sociophonetics, although not all are yet amenable to use on large speaker samples because of cost and/or invasiveness.

Speech Perception

Compared with work on production, less is known about the relationship between phonetic/phonological variation and speech perception. Thomas (2002a) provided a thorough review of perceptual work in sociophonetics, identifying five main types of work. First, a number of studies tested whether listeners can identify the social or regional background of speakers, based on exposure to the phonetic and phonological properties of their voices (e.g., van Bezooijen and Gooskens, 1999).

Second, a group of studies showed that phonological categorization may be influenced by the (assumed) social characteristics of the speaker. For example, Strand (1999) presented listeners with a continuum of synthetic stimuli ranging from a good [s] at one pole to a good [ʃ] at the other. The listeners' task was to label the stimuli as either /s/ or /ʃ/. As the stimuli were presented some listeners saw a female face while others saw a male face. The category boundary differed for the two listener groups, in line with typical differences in speech production: listeners who saw a female face placed the boundary at a higher frequency, since female voices typically produce fricatives with higher frequencies than male voices. Similar results were found by Elman *et al.* (1977). The third type of study assessed how native dialect impacts on perceptual categorization. Janson (1983), for instance, found that younger and older listeners in Stockholm had a different perceptual boundary to divide a continuum of synthesized Swedish vowels. The boundary was in line with differences in the production of the two groups.

Thomas's fourth group included investigations of whether listeners are able to perceive sound changes in progress, such as subtle splits in vowel quality (e.g., Di Paolo and Faber, 1990). The final group of experiments investigated how variation contributes to listeners' judgments about the personality of the speaker (e.g., Giles and Powesland, 1975).

Theoretical Implications

The wide variety of work that can be called sociophonetic has contributed in diverse ways to the development of linguistic theory. In sociolinguistics, the discovery of socially constrained variation has made a particular impact on understanding how linguistic change originates, and how it spreads through communities and grammars (e.g., Milroy, 1992; Labov, 1994–2001; Kerswill and Williams, 2000; Trudgill *et al.*, 2000). Labov's work on vowel formant analysis yielded influential models that aimed to explain and predict directions of long-term phonological change via universal principles, including chain shifting (for a critical review see Gordon, 2001). In particular it has been shown that certain individuals are more likely to adopt new variants than others because of their social position (e.g., the structure of their networks of interaction), physical and social mobility, and attitude. In the latter case, for example, an individual may be willing to adopt new pronunciations if such forms have a high "market value" in the workplace (Coupland, 1980).

Until recently, sociophonetic studies have made less of an impact on grammatical theory, which is unsurprising in view of the fact that modern linguistic theory has been preoccupied with the "ideal speaker-hearer in a homogeneous speech community." Variation has therefore not been a prime concern in the development of most phonological models. However, adjustments to the machinery of several phonological models have been made in response to the findings of sociophonetic work. These include Optimality Theory (e.g., Nagy and Reynolds, 1997), Government Phonology (Harris, 1994), and Lexical Phonology (McMahon, 1991). The recent emergence of exemplar theories of lexical representation, based primarily on psycholinguistic research, has also seen variation in both perception and production play a more central role (Pisoni, 1997; Pierrehumbert, 2002).

Applications of Sociophonetics

Sociophonetic work has an important contribution to a range of interests beyond linguistic theory.

Speech technology, for instance, must cater for social, regional, and contextual variation to generate natural-sounding synthesized speech and to ensure speech recognition systems can tolerate natural variation (Hoequist and Nolan, 1991). Descriptive accounts of systematic variation in speech are therefore of vital importance, as is testing of the perceptual evaluation of synthetic speech.

Speech and language therapists benefit from informed views of linguistic variation, enabling them to distinguish genuine pathology from natural, non-standard variation. Pedagogical issues are similarly informed by debate on phonological variation, most famously perhaps in the case of the 'Ebonics' debate in the United States (Wolfram and Schilling-Estes, 1998: 169ff.). Models of English for teaching as a foreign language are also constantly revised in line with changes in British and American standard varieties, as well as in response to the development of influential new standards, such as Australian in east Asia.

Information on variation is critical for casework in forensic phonetics, in which the commonest task is the comparison of a criminal recording (such as a threatening phone call) with a suspect's speech, to assess the likelihood that the suspect was indeed the speaker in the crime (Nolan, 1997). The strength of conclusion that can be reached is largely dependent on the state of descriptive reference material, including the likely geographical origins of particular features and the distribution of variable features across the relevant population.

Summary

Sociophonetics is very much a developing field with a wide remit. As it begins to take on its own shape and gain independence from its parent disciplines, it is apparent that its defining characteristic is a cross-fertilization of methods and theories which have their origins in distinct fields. As Thomas (2002b) pointed out, this enables sociophonetics to address the weaknesses in its components. It takes its material not only from standard dialects and careful speech, but also from spontaneous interaction. It combines highly controlled experimental designs with observation of speaking and listening in different everyday situations, often using large and heterogeneous samples of subjects. It employs detailed analysis using a variety of techniques. Its methods are informed by a variety of different theoretical models, and its results are in turn used to address a wide range of theoretical issues. This approach is allowing us to gain an ever more focused picture of what is probably the single most defining characteristic of human speech – its variability.

Overview of the Intracarotid Amobarbital Procedure

The intracarotid amobarbital test (IAT) was first described by Juhn Wada and thus is often referred to as the 'Wada test.' Wada originally developed this technique to study the interhemispheric spread of epileptiform discharges in patients undergoing unilateral electroconvulsive therapy. Based on his observation that an expressive aphasia resulted when the language dominant hemisphere was injected with amobarbital, he reasoned that this technique might be useful in determining hemispheric language dominance in neurosurgical candidates (and thus minimize speech and language dysfunction in patients undergoing dominant hemisphere surgery).

Since the exact nature of the amobarbital procedure varies from center to center (and some centers perform injections of vessels other than, or in addition to, the internal carotid artery that can also inform about language), this article restricts itself to a general description of the practice of this procedure and its underlying assumptions. In general, the IAT involves invasive carotid arteriography. During the IAT procedure, a catheter is positioned within the internal carotid artery, and amobarbital then is injected to anesthetize the majority of one hemisphere of the brain. Such an injection leads to pharmacological inactivation of brain areas in the distribution of the ipsilateral anterior and middle cerebral arteries, and the anterior choroidal artery. That is, a great deal of the frontal and temporal cortices is deactivated. Following the infusion of amobarbital, the patient carries out multifarious memory and language tasks. Since it is assumed that disruptions of language and memory during IAT are a consequence of the temporary 'lesioning' of the injected hemisphere, and that IAT mimics the effects that surgery on the injected hemisphere might have, the IAT allows one to predict the effect that surgery would have on each hemisphere. Of course, what is at issue is whether the uninjected ('intact') hemisphere could adequately support language and memory were the other hemisphere to be operated on. Although some centers inject only the hemisphere to be operated on, most centers also carry out the procedure on the other hemisphere to establish the extent of lateralization of function.

The Wada Test's Contribution to Neurolinguistics

The IAT bears several advantages as a research tool relative to traditional lesion studies. Specifically, it is possible to obtain baseline data in the individual to be studied, meaning language and memory performance is known in the 'prelesion' state; to compare lesion effects on both hemispheres in the same individual; and gather group data where the 'lesion'-to-assessment interval is relatively homogenous, thus minimizing maturational confounds, and the lesion is fully reversible. The disadvantages of the IAT entail the brevity of the drug effect and the possibly limited generalizability of findings. When gathering clinically relevant information is of paramount importance, there is, within the time constraints of the IAT, little opportunity to manipulate the nature of stimuli. Furthermore, because the IAT is carried out in individuals with typically chronic cerebral dysfunction (epilepsy), it is unclear whether findings obtained apply also to normal populations or even to groups with other neurological conditions. Nonetheless, the IAT has enabled researchers to explore not only intra- and interhemispheric differences in language representation and their correlates, but also, by looking at individuals with brain injury, the functional resiliency and plasticity of brain structures.

One domain of inquiry richly informed by IAT studies is the relationship between handedness and hemispheric language dominance. In most people, the left hemisphere is language dominant, but occasionally the right hemisphere is dominant or both hemispheres may participate in language on more equal footing. Although right-handedness is highly correlated with left hemisphere speech dominance in the population at large, brain abnormalities may interfere with the normal neuroanatomical organization of cognitive functions and involve reorganization. Specifically, IAT studies have shown that early brain injury is often associated with a shift in language dominance, but a shift in language dominance does not necessarily entail a shift in handedness, or vice versa.

Several studies have identified factors associated with shifts in language and handedness. Left hemisphere injuries sufficient to cause hemiparesis have been found to be associated with both left-handedness and right or bilateral speech representation. Among patients without hemiparesis, sinistrality and right or bilateral language representation were associated with the existence of extratemporal pathology. Left-handers with left hemisphere speech dominance

have also been found to be less likely to have had hemiparesis or extratemporal injuries. Extratemporal lesions and multiple or bilateral seizure foci have been found to be related to atypical speech representation. In addition, among left mesial temporal lobe epilepsy patients, atypical language lateralization has been found to be associated with higher spiking frequency on EEG. Thus, the location and extent of injury may be factors related to language shifts.

One of the most important factors underlying atypical language representation is the age at which brain injury occurs. Since the resiliency of the brain is maximal during the early years of life, it makes sense that injury at a very early age might induce either the intact or the damaged hemisphere to reorganize (i.e., accommodate speech and language zones) so as to compensate for functional losses. Intrahemispheric language reorganization has been found to be more likely than interhemispheric reorganization after the age of 6 years. Interhemispheric language reorganization is more likely to occur at earlier ages, but unfortunately, not without possible cost to nonverbal functions. Specifically, patients may experience a 'crowding' of nonverbal function. Evaluation of verbal and nonverbal functions during IAT in epileptic patients with early onset of left hemisphere dysfunction has revealed that patients with atypical (right hemisphere) speech representation perform as well as patients with left hemisphere speech on most measures of language function. However, patients with atypical speech patterns perform more poorly than 'left hemisphere' patients on nonverbal tasks. Transfer of language may 'crowd out' functions normally under the mandate of the right hemisphere. Thus, a right–left maturation gradient, characterized by a slower development of the right than left hemisphere, might permit the still more plastic right hemisphere to assume language functions, but not without disturbing the typical organization of right hemisphere functions.

Amobarbital studies of patients with epilepsy have also challenged the notion that hemispheric language dominance falls into discrete categories. Rather, it is more likely that language representation falls on a continuum from strongly left hemisphere dominant to strongly right hemisphere dominant, just as handedness seems to fall on a continuum from strongly dextral to strongly sinistral. However, other data suggest that cases might not fall along all points of such a continuum. Specifically, there are four major patterns of hemispheric speech representation. Toward the left-dominant end of the spectrum, there are indeed several clusters representing degrees of left speech dominance. However, individuals with bilateral or right speech dominance tended to center at these respective points, without the gradation observed for left hemisphere representation.

A limited number of amobarbital studies have addressed two other important issues, namely, the intra- and interhemispheric organization of language in bilinguals and the organization of sign language. With respect to studies of bilinguals, studies have consistently shown that the interhemispheric organization of both languages is complementary; i.e., hemispheric dominance for the two languages is similar. However, the intrahemispheric organization of the native and second language is likely different. On the basis of the observation that the patient's second language recovered before the native language after left middle cerebral artery amobarbital injection, the second language might be organized within the central sylvian core, whereas the first language might be represented in more distant perisylvian areas. One might, however, find a diametrically opposing interpretation to be more plausible. Electrical stimulation studies show that object naming in the first and second languages is differentially represented within the language dominant hemisphere. According to these studies, the second language is represented in a larger area, more peripheral from the Sylvian fissure. Thus, one might conclude, assuming that the effects of amobarbital dissipate earlier in more distant areas, that the first language is more centrally represented.

Sign language studies in nondeaf individuals also indicate hemispheric organization of sign and spoken language to be similar, at least insofar as the same hemisphere is dominant for both forms of communication. The existence of subtle interhemispheric differences in the organization of signed and spoken language, however, is not settled by amobarbital studies. On the one hand, some studies have found that sign language is characterized by greater bilateral representation than spoken language. In contrast, several other studies have found the interhemispheric organization of signed and spoken language to be complementary and highly similar.

Because a substantial proportion of deaf individuals apparently have experienced some cortical reorganization, reports of IAT test results in a deaf individual are of particular significance. That is, such studies provide tentative data about whether findings from normal-hearing individuals concerning the organization of sign language apply to deaf individuals. Complete left-hemispheric dominance has been found in a right-handed individual for American Sign Language, signed English, and finger spelling. Thus, evidence of bilateral representation for sign language was not found.

Amobarbital studies have also indicated that crossed aphasia (the occurrence of aphasia in right-handed

individuals after insult to the right hemisphere) should not necessarily be taken to imply right-hemispheric language dominance in these right-handers. Researchers have determined via IAT that their patients with crossed aphasia actually had bilateral language representation.

Functional Magnetic Resonance Imaging and the Future of the Intracarotid Amobarbital Test

Even though IAT continues to be the standard presurgical means of assessing lateralization of language and memory, its invasiveness and attendant risks have caused many to search for a less invasive method. Researchers have begun using functional magnetic resonance imaging (fMRI) as a noninvasive alternative to the IAT. fMRI allows visualization of changes in the flow of fluids in brain areas that occur over time spans of seconds to minutes. In the brain, blood oxygen level is assumed to be related to neural activity, and consequently fMRI can be used to infer brain activity changes when images of the brain are obtained while persons are engaged in tasks and compared to images obtained during rest or a comparison task. A variety of language and memory activation paradigms have been described. In general, fMRI determines hemispheric dominance through the use of laterality indices that compare the ratio of activated pixels (small areas within an image) in one hemisphere to those in the other. Alternatively, hemispheric dominance for a function can be inferred from comparisons of the activation of specific, homologous regions in each hemisphere, which may yield results more consistent with those of the IAT than does the derivation of global lateralization indices. Despite the fact that fMRI shows promise as a noninvasive alternative to IAT, its reliability in predicting postoperative memory function has not been sufficiently investigated. It remains unclear whether removal of a region activated in an fMRI image necessarily leads to inability to perform the related task. Hence, additional studies are needed before fMRI can be trusted for surgical planning.

Sogdian

P O Skjærvø, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Sogdian, an Eastern Middle Iranian language, was spoken at least up to the 8th century in Sogdiana, the area of modern Uzbekistan that includes the cities of Samarkand and Bukhara. Many Sogdians were merchants, however, and traveled east as far as China, bringing with them the Sogdian language. The Manicheans and Christians, as they fled from persecutions from the 3rd century on, took the Sogdian language with them to the farthest reaches of Chinese Turkestan and beyond, into Mongolia, where the Sogdian alphabet was adopted by the local Turks and the Mongolians, who still use it. The Sogdian written remains consist of religious and nonreligious texts. Most of the religious texts are translations, the Buddhist texts from Chinese, the Manichean ones from Persian and Parthian, and the Christian ones from Syriac.

We have Sogdian texts in five different alphabets: Old Sogdian Aramaic, Sogdian-Uighur (Uyghur), Manichean, Nestorian Christian, and Northern Brahmi. The Sogdian Aramaic script is used in the *Ancient letters* (see below) and in graffiti on rocks along the Karakorum Highway in northern Pakistan. The Sogdian-Uighur script is the most common, being used for secular documents, as well as for Buddhist and Manichean texts. The Manichean and Nestorian scripts were used for Manichean and Christian texts, respectively. There are a small number of late Sogdian manuscripts from Turfan written in Northern Brahmi script.

In early times, the Sogdians must have been the neighbors of the Tocharians (*see* **Tocharian**), who borrowed numerous (proto-)Sogdian words. The modern Iranian language Yaghnobi is the descendant of a Sogdian dialect different from the known Sogdian.

The oldest Sogdian texts are the *Ancient letters*, written on paper and discovered by the British-Hungarian discoverer and archeologist Marc Aurel Stein in eastern Chinese Turkestan (now in The British Library). The letters can be dated to the early 4th century by references to current events.

From the 8th century, we have a collection of letters and administrative, economic, and legal documents written in the Sogdian script from the archives of King Dhewastich found at Mount Mug east of Samarkand.

The largest corpus of Sogdian texts are the Buddhist texts removed from a cave at Dunhuang in eastern Xinjiang by Aurel Stein and the French scholar and archeologist Paul Pelliot (now in The British Library and the Bibliothèque Nationale). Numerous Sogdian Manichean and Christian texts were discovered at Turfan in northeastern Xinjiang by German archeologists (now in the Brandenburgische Akademie der Wissenschaften in Berlin).

Sogdian phonology and morphology are both conservative and innovative. The most important innovation is the 'rhythmic law,' by which words with long vowels before the endings ('heavy' stems), lose final short vowels. Thus, OIran. SING NOM **wrk-ah* and ACC **wrk-am* 'wolf' are Sogd. *wərk-í* and *wərk-ú* ('light' stem), while OIran. **daiw-ah* and **daiw-am* and **daiw-am* 'demon' are both *δḗw*. Sogdian shares with Ossetic the plural suffix *-t-* (originally a collective noun, hence declined like a feminine singular), for instance, *δḗw-t* 'demons'; forms of *δβar-* 'door': SING NOM *δβar-í*, LOC *δβar-yá*, PLUR NOM-ACC *δβar-t-á*, GEN-DAT, LOC *δβar-t-yá* 'at the doors'. Sogdian uses demonstrative pronouns as definite articles (*xō mártī* 'the man', *xā strīš-t* 'the women' [< *strīč-*], *uya kánθ-ī* 'in the city' [LOC]).

The verb system is complex. There are three stems: present, past, and perfect (perfect participle = past stem + suffix-*ē*, FEM-*č-a*; e.g., PRES *pətsā́č-* 'fit', PAST *pətsaγt-*, PERF MASC *pətsaγt-ḗ*, FEM *pətsaγ-čá-* [*-γt-č-*> *-γ-č-*]). It has all the Old Iranian moods (indicative, imperative, subjunctive, optative, injunctive), as well as active and middle. It has, in modified form, the old imperfect, for instance, PRES *βar-ám*, IMPERF *βar-ú* 'I carry, carried', PRES *wḗn-am*, IMPERF *wḗn* 'I see, saw', PRES *θaβr-ám*, IMPERF *θā́βr-u* 'I give, gave'. Progressive tenses are formed with the suffix *-skun* (*-sk*) and the future with the suffix *-kām* (*-kan*, *-k*) from a noun meaning 'wish' (IMPERF PROG *βar-á-skun* 'he was carrying', FUT *βar-ám-kām* 'I shall carry'; Christian Sogd. PRES PROG *γərb-ám-sk* 'I am seizing', FUT *wā́b-t-kan* 'he shall say').

There is a large range of past tense forms built on the remade Old Iranian perfect system: transitive active tenses with past stem plus the verb *δār-* 'hold, have' (e.g., *uγt-u-δā́r-t* 'he has said'), but intransitive and passive tenses with past stem plus copula (e.g., *tγat-ḗš* 'you entered', *ā́žit-əsθa* 'you were born').

The perfect is made with the perfect participle in the same way (e.g., *βast-ḗ δārand* 'bind-PERF.MASC hold.PRES-3RD.PLUR' = 'they hold/keep bound,' *βast-č-á astí* 'bind-PERF.FEM COP.3RD SING' = 'she is (now) bound'). The passive is made with the perfect participle plus 'be, become' (e.g., *βast-ḗ-t uβ-and* 'bind-PERF.MASC.PL become.PRES-3RD.PLUR' = 'they are being bound', *ánxast-ē əkt-ēm* 'goad-PERF.MASC become.PAST-COP.1ST SING' = 'I was goaded').

Among special formations, note the 'potentialis,' formed with a past participle with the ending (light) *-a* and the verbs *kun-* 'to do' (active) and *β-* 'become' (passive), by which possibility and completion of action are expressed (e.g., *nē žaγd-á kun-am* 'NEG uphold.PART do.PRES-1ST.SING' = 'I cannot uphold', *nē āpāt βō-t* 'NEG reach.PART become.PRES-3RD.SING' = 'it cannot be reached', *čānō xwart xurt kun-and* 'when food eat.PART do.IMPERF-3RD.PL' = 'when they had eaten').

There are minor dialect differences between texts written in the Sogdian, Manichean, and Nestorian scripts (e.g., Sogd. *wan-*, *kwn-* 'to do', Man., Chr. *kun-*). Christian Sogdian also has phonetically more developed forms (see also on the progressive and future above), e.g., **kərtu-δār-am* 'I did, I have done' > Buddhist Sogdian *əktu-δār-am* > Christian Sogdian *k-θār-am*.

Solomon Islands: Language Situation

B Palmer, University of Surrey, Guildford, UK

© 2006 Elsevier Ltd. All rights reserved.

The Solomon Islands (SI) is a former British colony bordering Papua New Guinea (PNG) in the southwest Pacific. Despite a population of only about 400 000, the country has 63 vernacular languages, many with several dialects. Seven are Papuan; the rest belong to the Oceanic branch of Austronesian.

Most of the country's languages belong to two separate branches of Oceanic: Southeast-Solomonic (SES) and Northwest-Solomonic (NWS).

SES is the largest group, with 26 languages accounting for 65.5% of the vernacular-speaking population. It is a conservative and clearly defined subgroup within Central/Eastern Oceanic, more closely related to the languages of Fiji, Polynesia, and Micronesia than to NWS. SES has two main branches, one centered on Guadalcanal and Gela, the other on Malaita and Makira.

NWS is a more complex group extending across the PNG border into Bougainville, with close links to languages farther west in PNG. Accounting for 22.5% of the population, SI's 19 NWS languages comprise three branches centered on Choiseul, Santa Isabel, and New Georgia, plus Mono-Alu, from a Bougainville-based branch.

Four further languages comprise Utupua-Vanikoro, a sister subgroup to SES within Central/Eastern Oceanic. Spoken in the remote Reefs-Santa Cruz islands, they account for 0.5% of the population. Another six languages, spoken on remote islands by 3.5% of the population, are Polynesian Outliers, the result of prehistoric back-migration from Polynesia. Finally, the Micronesian Kiribati language (Gilbertese) is spoken in several communities resettled from Kiribati in the 1950s (0.5% of the population).

The remaining seven languages divide into two possibly unrelated Papuan groups: Central Solomons and Reefs-Santa Cruz, each representing 4% of vernacular speakers.

This complex picture is the result of a complex linguistic history. At least 35 000 years ago the region was inhabited by Papuan speakers. As the easternmost limit of intervisible islands, SI probably represented the farthest reach of pre-Austronesian human settlement in the Pacific.

The first Oceanic settlement, around 1400 B.C., was rapid, probably giving rise to SES and Utupua-Vanikoro. A second, slower wave followed as Western Oceanic speakers spread into western SI, overlaying the earlier Oceanic stratum and giving rise to NWS. Over time, Oceanic languages largely displaced earlier Papuan languages. Contact between Oceanic and Papuan speakers brought lexical innovation in SES, and long periods of Oceanic/Papuan bilingualism contributed to grammatical innovation in NWS. In the Reefs-Santa Cruz islands, long coexistence between Papuan and Utupua-Vanikoro languages resulted in

The Solomon Islands (SI) is a former British colony bordering Papua New Guinea (PNG) in the southwest Pacific. Despite a population of only about 400 000, the country has 63 vernacular languages, many with several dialects. Seven are Papuan; the rest belong to the Oceanic branch of Austronesian.

Most of the country's languages belong to two separate branches of Oceanic: Southeast-Solomonic (SES) and Northwest-Solomonic (NWS).

SES is the largest group, with 26 languages accounting for 65.5% of the vernacular-speaking population. It is a conservative and clearly defined subgroup within Central/Eastern Oceanic, more closely related to the languages of Fiji, Polynesia, and Micronesia than to NWS. SES has two main branches, one centered on Guadalcanal and Gela, the other on Malaita and Makira.

NWS is a more complex group extending across the PNG border into Bougainville, with close links to languages farther west in PNG. Accounting for 22.5% of the population, SI's 19 NWS languages comprise three branches centered on Choiseul, Santa Isabel, and New Georgia, plus Mono-Alu, from a Bougainville-based branch.

Four further languages comprise Utupua-Vanikoro, a sister subgroup to SES within Central/Eastern Oceanic. Spoken in the remote Reefs-Santa Cruz islands, they account for 0.5% of the population. Another six languages, spoken on remote islands by 3.5% of the population, are Polynesian Outliers, the result of prehistoric back-migration from Polynesia. Finally, the Micronesian Kiribati language (Gilbertese) is spoken in several communities resettled from Kiribati in the 1950s (0.5% of the population).

The remaining seven languages divide into two possibly unrelated Papuan groups: Central Solomons and Reefs-Santa Cruz, each representing 4% of vernacular speakers.

This complex picture is the result of a complex linguistic history. At least 35 000 years ago the region was inhabited by Papuan speakers. As the easternmost limit of intervisible islands, SI probably represented the farthest reach of pre-Austronesian human settlement in the Pacific.

The first Oceanic settlement, around 1400 B.C., was rapid, probably giving rise to SES and Utupua-Vanikoro. A second, slower wave followed as Western Oceanic speakers spread into western SI, overlaying the earlier Oceanic stratum and giving rise to NWS. Over time, Oceanic languages largely displaced earlier Papuan languages. Contact between Oceanic and Papuan speakers brought lexical innovation in SES, and long periods of Oceanic/Papuan bilingualism contributed to grammatical innovation in NWS. In the Reefs-Santa Cruz islands, long coexistence between Papuan and Utupua-Vanikoro languages resulted in

Table 1 Speaker numbers for Solomon Islands vernacular languages in 1998 (Ethnologue)

More than 18 000	1
15 000–18 000	3
10 000–15 000	7
5000–10 000	15
1000–5000	25
500–1000	4
100–500	7
Fewer than 100	1

considerable mutual influence. More recently, Polynesian back-migration brought Outlier languages to small islands away from the main group.

Most SI languages have hundreds or thousands of speakers rather than tens of thousands (see Table 1). With 40% of the population, the Malaitan group contains the seven largest, with Kwara'ae (33 600) the only language with more than 18 000 speakers.

Multilingualism is the norm and code-switching common. Intermarriage between speakers of different languages is widespread, with communication often in Solomon Islands Pijin (SIP). Many smaller languages are seriously endangered, most losing ground to a few increasingly dominant vernacular languages. At least one Papuan language and three Oceanic languages have disappeared during the last century, and one is moribund.

The largest indigenous lingua franca is Roviana, with 16 000 second-language users. Over the past century, the role of vernacular lingua francas has steadily decreased in favor of SIP. Today, over 300 000 Solomon Islanders speak SIP as a supplementary language, and 15 000 speak it as their first language, securing its creole status. SIP is mutually intelligible with Tok Pisin (TP) (PNG) and Bislama (Vanuatu), the three forming Melanesian Pidgin. SIP is closer to English than are the other dialects, lacking the French element in Bislama and the German component and extensive vernacular source of TP.

Although SIP is almost universal in intergroup communication, it is typically viewed as 'broken' English by many speakers. Unlike TP and Bislama, SIP has no official status and is not used in education beyond the earliest years. However, it is the only language known throughout the country and is the language of urban life and of an emerging urban culture. English is the official language, used in government, courts, education, and most media, although SIP does appear in some media.

Somali

F Serzisko, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

Somali is a Cushitic language of the Afro-Asiatic language family spoken by approximately 10 million speakers in and around Somalia. There are five major Somali dialects (Lamberti, 1986).

Phonology

The following consonant phonemes are distinguished as shown in **Table 1**

There are five vowels: a, e, i, o, u and vowel length, in standard orthography indicated by doubling the vowels, is distinctive.

The following shows the letters used in Standard Somali orthography

IPA	ʔ	ʕ	ħ	ʃ	ɖ	x
Somali Orthography	′	c	x	sh	dh	kh

Tone appears to be distinctive in Somali both on the lexical level and on the grammatical level. It is, however, still a matter of debate whether this tonal distinction is really a tonal distinction or pitch accent (Hyman, 1981 for discussion).

Table 1 Speaker numbers for Solomon Islands vernacular languages in 1998 (Ethnologue)

More than 18 000	1

Somali is a Cushitic language of the Afro-Asiatic language family spoken by approximately 10 million speakers in and around Somalia. There are five major Somali dialects (Lamberti, 1986).

Phonology

The following consonant phonemes are distinguished as shown in Table 1

There are five vowels: a, e, i, o, u and vowel length, in standard orthography indicated by doubling the vowels, is distinctive.

The following shows the letters used in Standard Somali orthography

IPA	ʔ	ʕ	ħ	ʃ	ɖ	x
Somali Orthography	′	c	x	sh	dh	kh

Tone appears to be distinctive in Somali both on the lexical level and on the grammatical level. It is, however, still a matter of debate whether this tonal distinction is really a tonal distinction or pitch accent (Hyman, 1981 for discussion).

Table 1 Consonant phonemes

b		t d		ɖ		k g	q	
m			n					
					J			
			l					
			r					
	f		s		ʃ	x	ħʕ	h
w					y	(W)		

In terms of syllable structure, no word-initial or -final consonant clusters are allowed.

Morphology

Verbs

Somali has a rather rich system of lexical affixes by which new stems can be derived. The main derivational affixes are listed below.

Causative			
in jabay	'is broken'	*jab-i-yey*	'to break'
Stative/passive			
am jeex	'to tear'	*jeex-an'*	'to be torn'
Autobenefactive			
an wádayaa	'to drive'	*wadá-na-yaa*	'to drive for oneself'

The following examples demonstrate the use of these derivational affixes with the verb *fur* 'to open':

Wuu fúrayaa	'He is opening it.
Wuu fúrmayaa	'It's getting opened, it is opening'
Wuu furánayaa	'He is openening it for himself'

Morphosyntactic categories of the verb are tense, aspect, and person. There is also an inflectional distinction between main and subordinate predications.

The basic tense distinction is past/non-past, whereby non-past usually has a habitual meaning. Future is expressed by periphrastic construction with the auxiliary *doon* 'want'. There is furthermore an aspectual distinction between progressive and non-progressive.

	Past	Non-Past	
Non-Progressive			
Keen-ay	'brought'	*Keen-aa*	'brings'
Progressive			
Keen-ay-ay	'was bringing'	*Keen-ay-aa*	'is bringing'

The progressive form is historically derived from an auxiliary construction with the verb *hay* 'to have'.

The verb agrees with the subject in gender and number. Inflection is mainly done by suffixes (weak verbs) but there is a small group of five verbs that still have at least partly prefix conjugation (strong verbs). The following sample shows the main verbal forms for the weak and the strong verbs. It should be noted that at least in the main paradigms the forms for 1st and 3rd person masculine and the forms for 2nd and 3rd person feminine are identical.

A sample paradigm for the simple past is given for *keen* 'bring' and *yimi* 'come'

	Weak verbs 'bring'	Strong verbs 'come'
1st/3sm	*keenay*	*imid*
2nd/3sf	*keentay*	*ti-mid*
1pl	*keennay*	*nimid*
2pl	*keenteen*	*timaaddeen*
3pl	*keeneen*	*yimaaddeen*

Predicate negation is expressed by preverbal particles and verbal inflection. An invariable form is used for all persons in the past. The present form inflects regularly.

Past:	*Má keenín*	'I/you/he etc. didn't bring'
	má iman	'I/you/he/etc. didn't come'
Present:	*má keenó*	'I don't bring'
	má imaaddó	'I don't come'
	Má keentó	'she doesn't bring'
	má timaaddó	'she doesn't come'

Nouns

Nominal morphosyntactic categories are case, number, and gender. There is a twofold gender distinction based on masculine and feminine. Gender is marked by tonal distinction and by agreement on determiners like possessives, demonstratives, articles, and the verb. The masculine marker is basically *k* the feminine marker *t*. For a discussion of the status of these, see Lecarme, 2002.

Nin-ka	'the man'	*naag-ta*	'the woman'
inan-kayga	'my son	*gacan-tayga*	'my arm'

The basic distinction with number is singular/plural. Plural is marked by several means depending on the length and the gender of the noun. The following examples demonstrate the diverse plural forms.

	Singular	Plural
Woman	*náag*	*naago*
Road	*darìiq*	*dariiqyo*
Shoulderblade	*gárab*	*garbo*
Man	*nín*	*niman*
Bull	*díbi*	*dibí*
Story	*shéeko*	*sheekóoyin*
Father	*áabbe*	*aabbayaal*

There are mainly two cases: subject case and absolutive. The absolutive is the base form and the subject case is marked by a tonal distinction and optionally by the segmental elements *-i* with indefinite and *ku/tu*

with definite nouns. This subject marking occurs at the end of the entire noun phrase:

Buug-ga	*cusub*	*ee*	*wiil-kan-i*
Book-DET	new	COORD	boy-DEM-SUBJ
wux-uu	*yaala*	*miis-ka*	*guud-kiisa*
wax-3sm	located	table-DET	top-poss3sm

'The new book of this boy is lying on the table'

Possession is marked on the noun by pronominal suffixes: *aabe-hiis-a* 'his father'. If the possessor is expressed by a noun then the two nouns are juxtaposed and the order is possessee possessor: *faras-ka nin-ka* (horse man) 'the horse of the man'. Alienability is not expressed in Somali, with the exception that kin relationships cannot be simply juxtaposed but use an inverted construction where the possessor is additionally expressed: *ínanka aabi-hiis* 'the father of the boy' (lit. the boy his father). This construction is optional with other possessive relations.

Numerals are nouns and within the noun phrase they precede the noun and actually function as the head of the complex construction.

Laba nín	*sáddex nín*	*áfar nín*
'two men'	'three men'	'four men'

Adjectives

Qualitative concepts are expressed by elements whose status is not entirely clear (For a discussion, see the contributions in Bechhaus-Gerst and Serzisko (eds.), 1988). In predicative usage these elements occur with the copula:

Buug-gan	*waa*	*wanaagsán*	*yahay.*
Book-DEM	DM	good	COP:3sm

'This book is good.'

In attributive usage, adjectives may agree with their head noun in number; agreement is indicated by reduplication of the first syllable:

Guri cusub	'a new house'
guriyo cuscusub	'new houses'

The comparative is expressed by means of verbal case particles:

Nín-kanu	*nín-káas*	*wuu*	*ká*	*wèyn*	*yahay*
Man-this	man-that	DM	than(ABL)	big	COP

That man is bigger than that man.

The superlative is formed with the preverbal particle cluster *ugú*:

Nínkanu	*wuu*	*ugú*	*dhèer*	*yahay*
Man-this	DM	most	tall	COP

'This man is the tallest'

Syntax

The structure of a simple sentence can roughly be described as consisting of a verb complex, which contains all the necessary information, and noun phrases, which stand in a kind of appositive relation to this verbal complex. The structure of the verbal complex is as follows:

waa	Impersonal	object pronoun	case marker
directional	verb stem		

waa is a declarative marker that stands in complementary distribution with the negative marker. The declarative marker in main clauses, which has also been described as a verbal focus marker (see below), is the left-most element in the verbal complex. The next position may be filled by an impersonal marker. Object pronouns for 1st and 2nd person follow. The 3rd person object is always zero. These pronouns combine with the following case markers. Four cases are distinguished: benefactive /u/, locative/instrumental /ku/, ablative /ka/ and comitative /la/. The following shows the combinations of object pronouns and case marker for the singular pronouns:

	Benefactive	Loc/Instr	Ablative	Comitative
1st sing.	*ii*	*igu*	*iga*	*ila*
2nd sing.	*kuu*	*kugu*	*kaa*	*kula*

Directional particles indicate whether the action is directed toward the speaker /soo/ or away from speaker /sii/, as in the following examples.

w-aan	*ku*	*ark-ay*	'I saw you'
DM-1sg	2sgOBJ	see-1sg	
w-aan	*ku-gu*	*ark-ay*	'I saw you in it'
DM-1sg	2sgOBJ-LOC	see-1sg	
w-uu	*ku soo*	*noqd-ay*	'He came back to it.'
DM-3sm	LOC back	came-3sg	

The negation particle also occurs within the verbal complex:

I-i-ma	*soo*	*iibinin*
1sgOBJ-DAT-NEG	DIR	bought-NEG

'He didn't buy them for me.'

Sentence Structure

The most striking feature of Somali is the use of focus particle. Noun focus is expressed by the particles *ayaa/baa*, which are alternants whose use is determined by regional and stylistic factors, following the noun in focus. The particle *waa*, which has been described as a declarative marker above, is by some authors called verbal focus marker. Nominal

and verbal focus markers stand in complementary distribution, i.e., there can only be one focus marker in a main clause. The form of the focus marker is as a rule dependent on whether the noun in focus is the subject of the sentence or not. If the subject is in focus the marker occurs in its simple form and the predicate occurs in the restricted form. This indicates that the source of the focus construction may be a relative clause. If a non-subject is focused the subject pronoun combines with the focus marker, which yields the following paradigm of forms:

	Singular	Plural
1st sing	*ay-aan*	*ay-aynu/ay-aanu*
2nd	*ay-aad*	*ay-aad*
3rd masc.	*ay-uu*	*ay-ay*
3rd fem	*ay-ay*	

There is, furthermore, a presentative marker *waxa*, which also attracts the subject pronoun. This construction is used to highlight a nominal participant in a kind of clefting construction. The highlighted noun phrase occurs after the verbal complex.

Shaah b-aan doonayaa. 'I want some tea'
waxaan doonayaa shaah. 'What I want is tea'

Word Order

The unmarked word order in a main clause is SOV, the order of the nominal participants is relatively free and interacts with the focus marking system.

Nin-kii libaax-ii ayuu dilay 'The man killed the lion.'
Man-DET lion-DET FOC-3sg kill-3sg
Libaax-ii ninkii ayaa dilay 'The lion was killed by the man'
Nin-kii ayaa libaax-ii dilay 'It was the man who killed the lion'

Since there is an obligatory syntactic and morphological marking of aspects of discourse structure, Somali can be considered to be an example of a discourse configurational language (Svolacchia *et al.*, 1995).

Questions

Yes-No questions are formed by replacing the declarative marker *waa* by the question particle *ma*:

Cali wuu yimid. 'Ali came'
Cali ma yimid? 'Did Ali come?'

If the sentence contains a nominal focus the question particle is placed before the focused noun phrase:

Cali baa keenay. 'ALI brought it.'
Ma Cali baa keenay. 'Did ALI bring it?'

WH-questions always involve nominal focus and the questioned noun phrase stands with the interrogative article *kee/tee*:

Ninkee ayaa yimi? 'Which man came?'
Xaggee buu tegay? 'Which place did he go? = Where'
Sidee baad u sameysey? 'In which manner did you do it? = How'
Intee baad joogaysaa? 'What amount did you stay? = How long'

Complex Sentences

Complex sentences can be coordinated or subordinated. Clauses may be coordinated by the particle *oo* as in:

Cali hílibkíi ayùu keenay oo wàanu cunay
'Ali brought the meat and we ate it.'

Or they may be conjoined by attaching an element *-na* to the first element of the second clause:

Cali w-uu I arkay w-ùu-na
C. FOC-3s 1sgOBJ see-3sg FOC-3sm-COORD
i-lá had lay
1sgOBJ-COM speak-3sm
'Ali saw me and he spoke to me'

In subordinated clauses, there is no classifier or focus particle and the verb occurs in its subordinated form.

There is a formal distinction between restrictive and nonrestrictive relative clauses. The former are simply juxtaposed to the noun they qualify while the latter are coordinated by *oo*:

Nínkíi Soomáaliya ká yimí
'The man who came from Somalia . . .'
Nínkíi oo Soomáaliya ká yimí
'The man, who came from Somalia, . . .'

Complement clauses are introduced by the particle *in*:

In-uu imanayo ay-aan ogahay
Comp-3sm come-SUB FOC-1sg know-1sg
'I know that he is coming'

Adverbial clauses expressing temporal, local, and causal circumstances are formed with relative clauses to a noun like *marka* 'time'.

Markii aan casheynayay
Time-DET 1sg dining-PROG-PAST-1s
saaxiibkay baa soo galay
friend-POSS1sg FOC DIR come:in
'When I was dining my friend came in.'

Somalia: Language Situation

M Orwin, SOAS, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Of the many countries of Africa, Somalia, including the Republic of Somaliland in the north (which is not officially recognized by the international community), is unusual in that there is essentially only one language spoken throughout the whole country, namely Somali (*see* **Somali**). Somali speakers also live in the countries of Djibouti, Ethiopia, and Kenya. Some minority languages are spoken in Somalia by small numbers of people, but these have never had any official status and speakers of these languages have been persecuted during the destructive civil conflicts that have plagued the country over the last decade and a half. All speakers of minority languages also have some knowledge of Somali, whether Standard Somali or the local dialect.

Oromo is spoken in two regions: the Gedo region in the southwest and the lower Jubba region in the south. Another Cushitic language, Boni (or Aweer), more closely related to Somali, is spoken by a small number of people in the far south as well as in neighboring Kenya, and is in danger of becoming extinct in the not-too-distant future. Three Bantu languages are also spoken in Somalia: Mushungulu, spoken along the banks of the Jubba near the town of Jamaame, Ki-Bajuni, spoken in Kismaayo and along the nearby coast, and Chi-Mwini, spoken in Baraawe (Brava) and along the neighboring coastland. To what extent these languages are still represented in these areas is not known given the displacement of persecuted populations in Somalia and the small numbers of speakers.

Somali itself is made up of a number of dialect groups. Af Maxaad Tidhi, often referred to in English as the northern dialect group, is the most widely spoken by the predominantly pastoralist nomadic people of the northern, western, and southwestern regions of the Somali-speaking territories. In the region of the Jubba and Shabeelle rivers, where the people are mostly sedentary agriculturalists, the dialect groups May and Digil are spoken. The Banaadir group of dialects is spoken eastwards of the Shabeelle river to the coast and the Ashraaf dialects are spoken in Mogadishu and in the region around the town of Marka.

Somalia: Language Situation

M Orwin, SOAS, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Of the many countries of Africa, Somalia, including the Republic of Somaliland in the north (which is not officially recognized by the international community), is unusual in that there is essentially only one language spoken throughout the whole country, namely Somali (*see* **Somali**). Somali speakers also live in the countries of Djibouti, Ethiopia, and Kenya. Some minority languages are spoken in Somalia by small numbers of people, but these have never had any official status and speakers of these languages have been persecuted during the destructive civil conflicts that have plagued the country over the last decade and a half. All speakers of minority languages also have some knowledge of Somali, whether Standard Somali or the local dialect.

Oromo is spoken in two regions: the Gedo region in the southwest and the lower Jubba region in the south. Another Cushitic language, Boni (or Aweer), more closely related to Somali, is spoken by a small number of people in the far south as well as in neighboring Kenya, and is in danger of becoming extinct in the not-too-distant future. Three Bantu languages are also spoken in Somalia: Mushungulu, spoken along the banks of the Jubba near the town of Jamaame, Ki-Bajuni, spoken in Kismaayo and along the nearby coast, and Chi-Mwini, spoken in Baraawe (Brava) and along the neighboring coastland. To what extent these languages are still represented in these areas is not known given the displacement of persecuted populations in Somalia and the small numbers of speakers.

Somali itself is made up of a number of dialect groups. Af Maxaad Tidhi, often referred to in English as the northern dialect group, is the most widely spoken by the predominantly pastoralist nomadic people of the northern, western, and southwestern regions of the Somali-speaking territories. In the region of the Jubba and Shabeelle rivers, where the people are mostly sedentary agriculturalists, the dialect groups May and Digil are spoken. The Banaadir group of dialects is spoken eastwards of the Shabeelle river to the coast and the Ashraaf dialects are spoken in Mogadishu and in the region around the town of Marka.

Standard Somali, based on the northern dialect group, is used as a lingua franca throughout the Somali-speaking territories and is the language of broadcast and written media. This dialect group became a lingua franca prior to the introduction of Somali as the national language of the country (see below) since it was spoken by the nomadic population who were more widespread throughout the territories and whose oral poetry also became more widely known. Its use in radio, particularly by the Somali Section of the BBC World Service, means that it is understood by all Somalis.

Once the dialect was used as a national language, a lot of work was put into the development of words for concepts that had not previously been part of Somali life. The extension of the meaning of indigenous words and making compound words was one way in which this was achieved as, for example, in the use of *dayax gacmeed* for 'satellite,' where the literal meaning is 'hand-made moon.' Borrowings were also made from Arabic, which was already a source of loanwords, particularly in the spheres of religion (the Somalis are Muslims) and in trade, given the proximity of the Arabic speaking world to the Horn of Africa. Although there were official committees set up by the government in the 1970s to develop this new Somali terminology, the process was one that had already been started by broadcasters, particularly the Somalis who worked for the BBC, who had coined a large number of words prior to the development of an official script.

It was only in 1972 that Somali gained an official script, using the Latin alphabet chosen by the military regime of the time. This version, which was invented by Shire Jaamac Axmed, was based on other previous uses of the Latin alphabet, particularly that proposed by B. W. Andrzejewski and Muuse Galaal. Prior to that time Somali had been little written. In precolonial times written communication had been through the medium of Arabic or, very occasionally, in the idiosyncratic use of the Arabic alphabet for Somali, of which very few examples are known. During the colonial era the European languages, specifically English and Italian, were used for writing, and some indigenous scripts were invented at this time to write Somali. Of these indigenous writing systems the Osmaniya became the most widely used, although still limited.

Following independence the issue of choosing a national script was protracted due to the debate over which writing system to choose: Arabic, primarily for religious reasons; an indigenous script because it would be a genuinely Somali option; or the Latin script for predominantly practical reasons relating to typing and printing. The choice of the Latin script of Shire Jaamac Axmed proved to be fortuitous since Somali is now written without diacritics and can therefore be used very easily on the Internet where there are a great number of websites in the language. Once the Latin alphabet had been introduced the Somali language was made the official language of the country and ambitious literacy campaigns were started, initially in urban areas and subsequently in the countryside. The language was then used in education up to university level and in all administrative contexts.

Despite these efforts at developing literacy, the war with Ethiopia in the late 1970s, the developing civil conflict with the dictatorial regime in the 1980s, and continued unrest in the 1990s, with a total lack of central government everywhere except Somaliland, have all contributed to one of the lowest literacy rates in the world at 17.1% adult literacy (*Somalia Human Development Report 2001,* published by the UN Development Programme, p. 46).

Sommerfelt, Alf (1892–1965)

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Alf Sommerfelt was born in Trondheim, Norway. He studied Nordic and comparative Indo-European philology and Celtic languages in Oslo. In 1914, he went to Ireland. He spent one year there before going to France, where he stayed for seven years, mainly studying Celtic languages and general linguistics. From 1921 onward, he published several important contributions to Celtic dialectology and comparative Celtic philology.

In 1922, he returned to Oslo, and in 1926 he became lecturer and in 1931 professor of general linguistics, one of the first chairs in general linguistics in the world. Beginning in 1923, Sommerfelt was engaged in a large Norwegian lexicographic project (*Norsk riksmålsordbok*; Knudsen and Sommerfelt, 1937–1957). His interest in linguistics, which was inspired by de Saussure and Meillet, made him gradually turn away from Celtic studies toward general linguistics, where he was especially occupied with the social dimension of language. A milestone in his production is *La langue et la société* (1938), in which he not quite successfully tries to analyze a 'primitive' language in relation to the social and economic structure of the society where it is spoken. In the 1930s and the 1940s Sommerfelt published several important studies of the relationship between language and society that made him a pioneer of what later was labeled sociolinguistics (Sommerfelt, 1962).

In the 1930s Sommerfelt gathered the main Norwegian linguists (Bergsland, Borgstrøm, Morgenstierne, Stang, Vogt, etc.) once a month for seminars and dinner in his home. These meetings were of great importance for creating a good linguistic research milieu in Oslo, and due to Sommerfelt's international network the Norwegian linguists got first-hand knowledge of and contact with leading international linguists such as Louis Hjelmslev and Roman Jakobson.

During World War II, Sommerfelt worked at the Norwegian administration in London. After his return home he neglected to some extent his teaching and linguistic research. Instead he devoted most of his time to administrative duties at the University of Oslo and work related to UNESCO and Comité International Permanent des Linguistes where he for a long time was secretary general.

Sommerfelt was an undogmatic and theoretically diverse linguist. Through his seminars, he educated a whole generation of Norwegian linguists. In his own works, he combined structuralism with a sociolinguistic approach to language studies, being in that respect a pioneer.

Song Translation

P Low, University of Canterbury, Christchurch, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

What characterizes song as a genre is the combination of words and music, a combination that is fully realized in vocal performance. Although the most typical songs have short texts and relatively simple melodies, the genre is very diverse: a song may be (for example) a long narrative ballad, a sacred hymn, a complex aria from opera, a satirical jazz-song, or a repetitive chant for dancing.

From the standpoint of translating, two notable features about this genre are (a) the variety of specific purposes for which a translation might be sought, and (b) the very tight constraints imposed by one of these purposes, namely when the translation must itself be singable.

Sommerfelt, Alf (1892–1965)

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Alf Sommerfelt was born in Trondheim, Norway. He studied Nordic and comparative Indo-European philology and Celtic languages in Oslo. In 1914, he went to Ireland. He spent one year there before going to France, where he stayed for seven years, mainly studying Celtic languages and general linguistics. From 1921 onward, he published several important contributions to Celtic dialectology and comparative Celtic philology.

In 1922, he returned to Oslo, and in 1926 he became lecturer and in 1931 professor of general linguistics, one of the first chairs in general linguistics in the world. Beginning in 1923, Sommerfelt was engaged in a large Norwegian lexicographic project (*Norsk riksmålsordbok*; Knudsen and Sommerfelt, 1937–1957). His interest in linguistics, which was inspired by de Saussure and Meillet, made him gradually turn away from Celtic studies toward general linguistics, where he was especially occupied with the social dimension of language. A milestone in his production is *La langue et la société* (1938), in which he not quite successfully tries to analyze a 'primitive' language in relation to the social and economic structure of the society where it is spoken. In the 1930s and the 1940s Sommerfelt published several important studies of the relationship between language and society that made him a pioneer of what later was labeled sociolinguistics (Sommerfelt, 1962).

In the 1930s Sommerfelt gathered the main Norwegian linguists (Bergsland, Borgstrøm, Morgenstierne, Stang, Vogt, etc.) once a month for seminars and dinner in his home. These meetings were of great importance for creating a good linguistic research milieu in Oslo, and due to Sommerfelt's international network the Norwegian linguists got first-hand knowledge of and contact with leading international linguists such as Louis Hjelmslev and Roman Jakobson.

During World War II, Sommerfelt worked at the Norwegian administration in London. After his return home he neglected to some extent his teaching and linguistic research. Instead he devoted most of his time to administrative duties at the University of Oslo and work related to UNESCO and Comité International Permanent des Linguistes where he for a long time was secretary general.

Sommerfelt was an undogmatic and theoretically diverse linguist. Through his seminars, he educated a whole generation of Norwegian linguists. In his own works, he combined structuralism with a sociolinguistic approach to language studies, being in that respect a pioneer.

Song Translation

P Low, University of Canterbury, Christchurch, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

What characterizes song as a genre is the combination of words and music, a combination that is fully realized in vocal performance. Although the most typical songs have short texts and relatively simple melodies, the genre is very diverse: a song may be (for example) a long narrative ballad, a sacred hymn, a complex aria from opera, a satirical jazz-song, or a repetitive chant for dancing.

From the standpoint of translating, two notable features about this genre are (a) the variety of specific purposes for which a translation might be sought, and (b) the very tight constraints imposed by one of these purposes, namely when the translation must itself be singable.

Songs are often translated, partly because the ability of their tunes to cross linguistic frontiers prompts curiosity about their words. Thus translations exist for thousands of songs and hymns, and hundreds of extended entertainments based on song (operas and musicals). Yet few of the translators have said very much about their objectives and strategies, and little scholarly attention has been given to translating this genre.

Certain problems of song translation derive from the nature of the texts, for example, the use of metaphor, rhythm, rhyme, and raw emotional utterance. These features are encountered also in poetry translation (in fact, many song-texts began life as poems, being set to music later, whether or not that was the poet's intention). Other problems, however, relate to the essence of song as a performance genre. These problems are greatest when the translated text (TT) is itself meant to be sung, in which case numerous requirements must be met, as will be explained shortly. In many cases, however, notably in the classical music tradition, a song will be performed in a language unfamiliar to the audience, and so a TT is needed not for singing but for speaking, reading, or studying. Because these requirements are different, there are different types of song translating, according to the function that the translation is intended for.

Here are the five main functions that a song translation may have:

1. To be sung in the target language
2. To be spoken as an introduction to the original song
3. To be read in a recital program or a CD insert
4. To be studied by the singer preparing to perform the song in the source language
5. To be displayed as surtitles while the song or opera is being performed, or as subtitles on a videoed performance.

The present article will focus first on (1) before surveying the other possible functions. Comparison of these functions highlights the general truth that all translating is *ad hoc* and shows that a TT devised with one purpose in mind is unlikely to be ideal for another purpose.

Singable Translations

"It is impossible, of course, to translate any song verbatim: it simply won't fit the music in the other language," says Gene Lees, an expert on jazz song. He adds: "What one has to do is to understand the song's essential spirit and reconstruct it as closely as possible in the second language" (1998: 222).

The devising of singable texts is a particular challenge to a translator: one is subject to huge, multiple constraints imposed by the pre-existing music, which has its own rhythms, note-values, and stresses that one cannot simply ignore. Besides, the text often rhymes, and so rhyme is often desirable in this kind of song-translating (though not in others). Furthermore, when translating into English, one must seek to reduce the number of short vowel-sounds – unsuited to long notes – and the clustering of consonants, which can create tongue-twisters. Ideally, the TT must give the impression that the music has been fitted to it, even though it was actually composed to fit the original. Various translators have likened this task to solving a crossword puzzle – which suggests, among other things, the challenge of difficulty. A recent paper compares it rather to a pentathlon in which the translator is judged on five 'events': singability, sense, naturalness, rhythm, and rhyme (Low, 2003b).

Yet such translating is often attempted. One well-documented case is the songs of Georges Brassens, a popular French wordsmith whose rich, amusing, provocative texts might seem too daunting to tackle. They are not, as is shown in the collection *Traduire et interpréter Georges Brassens*, where various authors discuss making singable translations into English, German, Swedish, Czech, Dutch, Italian, etc. For example, a fine practical article by Andrew Kelly gives this advice to the translator: "(1) Respect the rhythms; (2) Find and respect the meaning; (3) Respect the style; (4) Respect the rhymes; (5) Respect the sound; (6) Respect your choice of intended listeners; and (7) Respect the original" (1992–1993: 92).

Because of the constraints imposed by the pre-existing music, song translators resort to numerous methods in order to overcome the difficulties they encounter. These include not only things like paraphrase, transposition, and modulation – which are fairly standard methods – but also devices like those mentioned by translators of Brassens: replacement metaphors, compensation in place, calque, omission, explicitation, cultural adaptation, superordinates, stylistic equivalence, the suppression of difficult verses, the use of added words to solve rhythmical problems, and the replacement of rhyme with assonance. The best song-translators use a toolbox plus a 'box of tricks'!

The results are seldom close to that semantic equivalence that receives high priority in most prose translation. But at best they can creatively deliver what some theorists call equivalent effect – or what Lees calls "the song's essential spirit." This phrase sums up the song-translator's objective. It is not well served by pedantic rules such as 'Never ever alter the rhythm' or 'Retain

the identical number of rhymes.' It is better served by taking the whole song as the 'unit to be translated' and by creative use of the methods just mentioned. Fortunately, the musical dimension of the source is being retained in performance, so that the TT will be transmitted in conjunction with the same non-verbal code that accompanied the source text (ST).

Singable translations are used much less in classical music than in popular music. Two reasons for this difference are the strong claim of the ST and the inadequacy of many available translations. One singer who has criticized translations like these ones is Arthur Graham, who stresses the point that: "The singer needs words that may be sung with sincerity" (Graham, 1989: 35). His emphasis on singability parallels a notion that is widely accepted in the translating of drama, that 'effectiveness on stage' is a practical necessity and must receive priority.

One kind of song-translating is itself a kind of drama-translating: the making of singable translations for operas or other works of musical theater. The bibliography mentions several articles that explore this complicated subject – Apter (1985), Gorlée (1997), Herman and Apter (1991), and Irwin (1996). Apter and Herman, writing as opera-translators, argue strongly that a very flexible translating strategy is essential for practical success on stage.

A Spoken Introduction

Sometimes a singer or presenter reads aloud a TT before the song is performed in the foreign language. This reading may be a full version of a short text, or a précis of a longer one. Some radio stations broadcasting classical songs use brief introductions giving the gist of the verbal content. Such a text has to communicate quickly and directly (re-reading is not possible). Good examples tend to be informal, brief, and clear.

A Program for Audience Members

Frequently the printed program for a concert gives translations of the foreign texts. The expectation is that audience members may consult this program before or during the performance. Sometimes recital programs print the ST also, in a parallel or 'facing-page' format, for the sake of those who have some familiarity with the source language.

Given the context, there is a good case here for a clear communicative translation, understandable at a glance. One translation expert advocates "sober, close, 'plain prose,' parallel, line by line translations" (Newmark, 1998: 21).

Similarly, recordings of classical vocal music almost always print translations, with or without the original words. This information enables the listener to read a TT while listening to the recording, or else to study it at another time, comparing it with the original. Some CD inserts print parallel texts in two languages or more. This context may be viewed as slightly different from the recital room, and as permitting a more literary TT (Low, 2003a).

A Performers' Crib

Editions of vocal music commonly print translations for the singer to use as a crib while rehearsing the song. These TTs may appear near the start of the volume, at the start of each song, or in the end papers. Often such translations are presented in parallel format; sometimes the layout is interlinear.

Such translations always present the text line by line, aiming thus to enlighten the singer about the meaning and function of every word. The objective is study, not easy reading – since the singer wants to know deeper meanings that will shape the artistic interpretation.

One of the best-selling collections of song translations focuses on this function. *Lieder line by line, and word for word* by Lois Phillips adopts a double strategy of providing both a pedantically close version (in interlinear format) and a clear prose version intended "to disentangle the often unintelligible series of words resulting from a literal word-for-word translation" (1979: vi). The former version is designed to help people to engage with the German words and word order; the latter to give a better sense of the whole poem.

Such translations made for study purposes may (and sometimes do) use informative footnotes to explain complexities and allusions in the source text. Providing such information is an appropriate role for the translator as cultural go-between.

Surtitles at a Performance

A surtitle is a caption displayed above the stage during a live performance, giving a written translation of the audible words – though not all of them – that are being sung at any given moment. Similar to the subtitles that are a standard means of translating films, surtitles are now common in the presentation of operas. Opera-goers have become accustomed to glancing up at the titles periodically, rather like drivers checking the rear-vision mirror – they have incorporated this habit into the set of conventions that go with the genre. In addition, surtitles are

sometimes used for song recitals and other musical performances.

Translating for the purpose of surtitles has many similarities to film subtitling. There are some differences, however, that are explored in two recent articles (Sario and Oksanen, 1996; Low, 2002). The main difference is that, if anything, one should make surtitles even less obtrusive than film subtitles, so that the words draw less attention away from the musical and visual aspects of the performance. Good surtitles will generally be simple, clear, and economical.

Particular constraints are imposed by the size of the screens displaying the surtitles. Legibility requires large lettering, with few characters per line. These constraints of size, though irksome, are not inimical to good surtitling. Once one grasps that the titles need not render every word, then one's objective becomes an attainable one: to provide visible 'sight-bites' that help the audience to understand. Unimportant adjectives are frequently cut; long words are avoided if possible; repetitions are largely ignored. Often one boils down long sentences into a condensed gist translation.

The actual translating is best done not from the bare words but from the musical score. Although a surtitler does not need advanced skills in score-reading, it is important to see the ways in which the composer has set the words, and particularly the tempo. Words that are sung rapidly need to be translated very economically.

Surtitling is therefore one of various forms of song translation where considerations like respect for the semantic and stylistic integrity of the ST, often important in translation, may be overruled.

Songhay Languages

G J Dimmendaal, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

The name Songai (also Songhay, Songhai, Sonrai) refers to a range of lects spoken mainly along the Niger River in Mali and Niger, as well as in Burkina Faso, and centering around major towns in the area. There are three major varieties: Western Songai (which includes Koyra Chiini, the town language of Timbuktu, and Djenne Chiini, spoken in Djenné), Central Songai (which includes Humburi Senni, with Hombori as the major city, and Kaado), and Eastern Songai (with Koyraboro Senni as a major lect) with Gao as a major urban centre. The Gao variety has been designated as the standard for Songai in Mali. The total number of speakers in these countries is estimated to be at least 1.1 million. Zarma (Dyerma), which is spoken by some 2 million people mainly in Niger and Nigeria, and Dendi, with around 72 000 speakers mainly in Niger and Benin, are closely related, but constitute separate languages. In addition, there are varieties in Mali and Algeria

sometimes used for song recitals and other musical performances.

Translating for the purpose of surtitles has many similarities to film subtitling. There are some differences, however, that are explored in two recent articles (Sario and Oksanen, 1996; Low, 2002). Songhay Languages

G J Dimmendaal, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

The name Songai (also Songhay, Songhai, Sonrai) refers to a range of lects spoken mainly along the Niger River in Mali and Niger, as well as in Burkina Faso, and centering around major towns in the area. There are three major varieties: Western Songai (which includes Koyra Chiini, the town language of Timbuktu, and Djenne Chiini, spoken in Djenné), Central Songai (which includes Humburi Senni, with Hombori as the major city, and Kaado), and Eastern Songai (with Koyraboro Senni as a major lect) with Gao as a major urban centre. The Gao variety has been designated as the standard for Songai in Mali. The total number of speakers in these countries is estimated to be at least 1.1 million. Zarma (Dyerma), which is spoken by some 2 million people mainly in Niger and Nigeria, and Dendi, with around 72 000 speakers mainly in Niger and Benin, are closely related, but constitute separate languages. In addition, there are varieties in Mali and Algeria

whose grammatical structure is similar to Songai, but whose lexical structure is rather deviant. Their speakers, who are culturally Tuareg, are known under a variety of names, e.g., as Tasawaq or Tadaksahak in Mali, and Korandjé in Algeria.

According to Greenberg (1963), Songai constitutes one of the six primary branches of the Nilo-Saharan phylum. Nicolaï (1990) has argued that Songai is nongenetic in origin, with a Tuareg (Berber) variety playing a major lexifying role. The documentation of the Songai cluster has improved dramatically as a result of a series of monographs by Nicolaï (1981) and Heath (1998, 1999a, 1999b).

The spreading of the Songai lects probably is related to the expansion of the Song(h)ai Empire from the 9th century until the late Middle Ages. Areal contact with neighboring languages belonging to different language families, such as Mande, Kwa, Gur (all Niger-Congo), and Berber (Afroasiatic) appears to have resulted in considerable typological variation within this cluster. Thus, whereas Central Songai varieties such as Humburi Senni or Kaado are tonal, western varieties such as Koyra Chiini appear to be nontonal. Also, in Western Songai varieties, SVO order appears to be common, with markers for mood, aspect, and negation occurring between the subject and the verb, and with complements other than the object following the verb. However, the object precedes the verb in Central and Eastern Songai varieties, which also use a transitive marker before the object noun phrase. All Songai lects appear to use postpositions. Nominal modifiers tend to follow the head noun, but possessors precede the latter. The use of a one-term deictic marker appears to be a more common areal phenomenon, also attested in neighboring Mande languages. Affixational morphology is somewhat restricted (derivational morphology in the verb, for example, appears to involve mainly causative and centripetal marking), but cliticization of morphemes is highly common in Songai, frequently resulting in a mismatch between phonological and grammatical words. Logophoric marking, as a reference tracking mechanism and evidential hedging strategy, is also used across sentence boundaries; compare Heath (1999a: 322–328).

Sonnenschein, Edward Adolf (1851–1929)

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Edward Adolf Sonnenschein was born in London, England, on November 20, 1851. He studied at London and Oxford Universities, graduating in classics in 1875. From 1877 to 1881 he worked in Glasgow, and in 1881 he was appointed head of Kelvinside Academy, but he resigned within the year. In 1883 he was made Professor of Latin and Greek at Mason College, Birmingham. Together with J. P. Postgate, he founded the Classical Association – in the defence of classics – in 1903. Sonnenschein died on September 2, 1929.

Sonnenschein's main linguistic work was done in Latin philology, grammatical terminology, and comparative Indo-European syntax, but he also engaged in the political debates of his day. His work on Latin covered editions of Plautus, studies of the subjunctive, and Latin metre. His terminological work falls into two main periods – the first from about 1886 to 1899, the second from about 1909 to the 1920s. *The soul of grammar*, his contribution to comparative Indo-European syntax, appeared in 1927.

In his brush with schoolteaching, Sonnenschein was struck by the wide variation in grammatical terminology: he asked "Why should verbal forms . . . be called by as many different names as there are languages in which they are studied?" (*Journal of Education*,

whose grammatical structure is similar to Songai, but whose lexical structure is rather deviant. Their speakers, who are culturally Tuareg, are known under a variety of names, e.g., as Tasawaq or Tadaksahak in Mali, and Korandjé in Algeria.

Sonnenschein's main linguistic work was done in Latin philology, grammatical terminology, and comparative Indo-European syntax, but he also engaged in the political debates of his day. His work on Latin covered editions of Plautus, studies of the subjunctive, and Latin metre. His terminological work falls into two main periods – the first from about 1886 to 1899, the second from about 1909 to the 1920s. *The soul of grammar*, his contribution to comparative Indo-European syntax, appeared in 1927.

In his brush with schoolteaching, Sonnenschein was struck by the wide variation in grammatical terminology: he asked "Why should verbal forms . . . be called by as many different names as there are languages in which they are studied?" (*Journal of Education*,

1886: 169). Why couldn't the terminology of grammar be simplified and unified? Out of this simple idea Sonnenschein developed the 'Parallel Grammar Series' (PGS), a set of textbooks written to a scheme not unlike Ratke's, ensuring uniformity of terminology and classification and of scope, size, and type. When the series was officially complete (more volumes were added later) it comprised over 25 volumes covering eight languages.

After the turn of the century, Sonnenschein conceived the idea of forming a Joint Committee on Grammatical Terminology (JCGT), with representatives from eight professional associations, to further the cause. The JCGT reported in 1911 and converted itself into a standing committee to monitor the reforms.

Despite opposition (e.g., Arnold, 1910) the JCGT co-operated with like-minded colleagues in other countries, notably France and the United States (Hale, 1913). As with the PGS, Sonnenschein published grammars of his own to promote the new terminology. By the 1920s Sonnenschein had extended his scheme to include six further 'oriental' Indo-European languages (Oriental Advisory Committee, 1920).

Sonnenschein's last major publication, *The soul of grammar*, pointedly borrowed its title from Jespersen (1924: 344–347). It consists of two major parts, one devoted to 'case and case-phrases,' the other to 'moods and tenses.' Here, Sonnenschein argued that "There is . . . such a thing as a common Indo-European syntax" (Sonnenschein, 1927: 115) and tried to make a case for cases in English (six in all). Jespersen, like Sweet, would have said that English has no case in any conventional sense (cf. Hudson, 1995).

It is a mark of Sonnenschein's success that many elementary textbooks at the end of the 20th century had still not reduced the number of cases they postulate to fewer than four.

Sorbian

G H Toops, Wichita State University, Wichita, KS, USA

© 2006 Elsevier Ltd. All rights reserved.

Sorbian is one of three branches of the West Slavic languages comprising Lower Sorbian and Upper Sorbian (the other two branches being the Czech-Slovak and the Lechitic). 'Sorbian' thus serves as a convenient cover term for one or both of the Sorbian literary languages and their respective dialects. The Lower Sorbian (hereafter, LSo) and the Upper Sorbian (USo) literary languages constitute supradialectal norms generally used in writing and public or mass communication (print media, radio, and television); in informal settings Sorbs (both Lower and Upper) tend to speak the dialect characteristic of their native village, with occasional admixtures of literary elements and German vocabulary. Sorbian as defined here is spoken today as a native language entirely within the borders of the Federal Republic of Germany (from 1949 to 1990, within the borders of the former German Democratic Republic); more precisely, it is spoken completely within the eastern German region of Lusatia (LSo *Łužyca,* USo *Łužica,* German *die Lausitz*), situated partly in the German state of Saxony (*Freistaat Sachsen*) and partly in the state of Brandenburg (see **Figure 1**). The Brandenburg portion includes what is traditionally known as *Lower Lusatia* (German *Niederlausitz*), while the Saxon portion includes most of *Upper Lusatia* (German *Oberlausitz*). These geographic designations are sometimes applied to the languages spoken there, whence the terms 'Lower Lusatian' and 'Upper Lusatian' in lieu of 'Lower Sorbian' and 'Upper Sorbian,' respectively. The Sorbian-language area, like the Sorbian speech community itself, has shrunk considerably in the past 100–150 years, so that it now extends at most only about 90 kilometers north-south and some 55 kilometers from west to east inside Lusatia proper. The Lower Sorbs call themselves *Serby* in their own language but reveal a preference for the appellation *Wenden* 'Wends' in German; the Upper Sorbs call themselves *Serbja* (*Sorben* [or, more specifically, *Obersorben*] in German). Descendants of Sorbs (now all English-speaking) who settled in the American state of Texas (some 60 kilometers east of the state's capital city, Austin) in 1854 describe their heritage as 'Wendish.' As far as anyone has determined, all Lusatian Sorbs – to the extent that they still speak some form of Sorbian – are bilingual in Sorbian and German and have been so since the early decades of the 20th century. Partly as a result of this universal bilingualism, ethnic Sorbs have tended increasingly to become unilingual German-speakers.

Estimates of the current number of native Sorbian speakers vary. An ethnosociological poll conducted by the Institute of Sorbian Ethnography (*Institut za serbski ludospyt*) in 1987 suggested 67 000 as the maximum number of Sorbian speakers in both Lower and Upper Lusatia (Faska, 1998: 20). A more recent compendium of USo grammar puts the number of USo speakers at no more than 53 600 (Schaarschmidt, 2002). Assuming that such estimates are accurate, one is led to surmise a maximum of 13 400 speakers of LSo (67 000 minus 53 600), a figure that is not substantially at odds with the estimate of 16 000 LSo speakers cited by Šatava on the basis of data also collected in 1987 (Šatava, 1994: 198). The overwhelming majority of today's native LSo speakers are more than 60 years old; consequently, the LSo dialects are expected to be extinct within the next 15–25 years (Jodlbauer *et al.*, 2001: 204). Schaarschmidt reckons that USo should be extinct by the year 2070; however, given current efforts at language maintenance, the USo literary language and at least some of its dialects (notably the so-called 'Kamjenc' [German: Kamenz] dialect of the approximately 15 000 Catholic Sorbs northwest of Budyšin [Bautzen]) stand a good chance of surviving well beyond the year 2100 (Schaarschmidt, 2002: 5–6).

The center of LSo literary and cultural activity (including radio and television broadcasting) is the city of Chośebuz (Cottbus); the center of USo literary and cultural activity is the city of Budyšin (Bautzen). This reflects the emergence of these two cities as 'dialect centers' in the 17th–18th centuries, owing to the fact that: (a) the majority of those educated Sorbs who translated (mostly religious) texts from German into Sorbian hailed from, or from the vicinity of, these cities; and (b) these cities already occupied major economic and political positions in Lusatia at that time. The first cohesive text written in Sorbian that we know of is the so-called 'Budyšin Oath' (*Budyska přisaha*) or 'Wendish Citizen's Oath' (*Bürgereid Wendisch*) dating from the year 1532. The early production of longer Sorbian texts is connected with the spread of the Protestant Reformation in Lusatia and the ensuing Thirty Years' War (1618–48). The first Sorbian religious text, as far as we know, is an eastern LSo translation of the New Testament of Martin Luther's Bible, which was written by hand in 1548. The first Sorbian printed book is a LSo collection of church hymns and a small Lutheran catechism published by the preacher Albin Moller in 1574. The first printed book in USo is a translation of

Figure 1 Sorbian speech communities. Schiller K J and Thiemann M (1979), *Stawizny Serbow* (vol. 4), Bautzen: Domowina, with permission.

the Lutheran catechism published by the preacher Wenzeslaus Warichius in 1587. Such 16th-century texts already exhibited varying degrees of German lexical and grammatical influences (e.g., Sorbian use of the demonstrative pronoun/adjective as a reflection of the German definite article).

Because Protestantism did not completely take hold among the Upper Sorbs, Budyšin emerged as a dialect

center only for the USo Protestants; among the USo Catholics, the dialect spoken in and around Kulow (Wittichenau) emerged in the 17th century as the basis for a Catholic variant of a nascent USo literary language. The dialectal basis for this variant eventually broadened in the direction of a West Sorbian Catholic dialect situated in the vicinity of Chrósćicy (Crostwitz). Thus, by the 18th century, two literary languages – one of them with two variants – existed among the Sorbs: LSo, Protestant USo, and Catholic USo.

Like German books printed at the time, the earliest Sorbian publications were printed in German blackletter, or Fraktur. Sorbian spelling was based on sound correspondences with German graphemes or phonetic approximations of them. Thus, the German trigraph **ſch** might correspond to the graphemes *ř, š,* or even *ž* (representing palatal continuants) in today's USo orthography. The palatal affricates, in contrast, were graphically influenced to some extent by Polish – **cz** was used where today one finds USo *č* or *ć*. For example, in Warichius's catechism of 1597, we find **The dzeſacz kaſni Bohſche** (in contemporary USo orthography: *Te dźesać kazni Bože*) 'God's ten commandments' (cf. Schuster-Šewc, 1967: 52). Around the middle of the 19th century, efforts were made to reconcile the Catholic and the Protestant variants of literary USo by standardizing their orthographies. The resulting orthography, set forth in the 1848 publication of *Hornjołužiski serbski prawopis z krótkim rěčničnym přehladom* ('Upper Lusatian Sorbian orthography with a brief grammatical overview') by Christian Traugott Pfuhl (Křesćan Bohuwěr Pful), incorporated Czech and Polish conventions – use of diacritics like the Czech háček (*č, ě, ř, š, ž*) and the Polish acute accent (*ć, dź, ń, ó*) as well as the Polish velar *l* (*ł*) – and was therefore labeled 'analogical.' The new orthography, however, was also **etymologically** based, introducing graphemes – particularly in word-initial consonant clusters – that had no phonetic value: *łowa* → *hłowa* 'head,' *cyć* → *chcyć* 'to want,' *dźe* → *hdźe* 'where,' *zać* → *wzać* 'to take.' On the one hand, the etymologically based orthography has since led to a number of artificial spelling pronunciations; on the other hand, it has made written USo more readily interpretable for those familiar with other Slavic languages. Moreover, it disambiguates a large number of homophones – e.g., *wóz* 'wagon, car,' *łós* 'elk,' *hłós* 'voice,' and *włós* 'hair' – all of which are pronounced [u̯úˀs]. LSo remains less reflective of etymology, cf. LSo *cu* 'I want,' *źo* 'there,' *ned* 'right away,' and *cora* 'yesterday' vs. USo *chcu, hdźe, hnydom,* and *wčera,* respectively. An USo spelling reform was introduced again in 1948. Several USo orthographic conventions have been adopted for LSo (*inter alia,* representing palatalization by means of the letter *j* rather than an acute accent—*ńod-* → *mjod* 'honey,' *ńasć* → *njasć* 'to carry'; cf. Schuster-Šewc, 1996: 253 and 260). LSo influence on USo spelling can be seen in the substitution of word-initial *ch* for earlier *kh* (USo *khodźić* → *chodźić* 'to go'; LSo *chójźiś* 'idem').

Today's USo alphabet consists of the following graphemes: *a, b, c, č, d, dź, e, ě, f, g, h, ch, i, j, k, ł, l, m, n, ń, o, ó, p, r, ř, s, š, t, ć, u, w, y, z, ž.* The letters *v* and *x* occur in foreign names. The letters *č* and *c′* represent the same phoneme /tʃ/ while reflecting different etymologies; the same holds true for the letters *ł* and *w* (phonetically [u̯]). The letter *ř* occurs only after *k, p,* and *t* and is pronounced like *š* except where *tř* constitutes a digraph representing the phoneme /c′/ (e.g., *tři* /c′í/ 'three'). Today's LSo alphabet includes: *a, b, c, č, ć, d, e, ě, f, g, h, ch, i, j, k, ł, l, m, n, ń, o, p, r, ŕ, s, š, ś, t, u, w, y, z, ž, ź.* Unlike USo, LSo alphabetizes *ch* with *c*, rather than after *h*. In 1995, the LSo Language Commission relegated *ó* (phonetically [ɛ] or [y] after labials and velars) to language-teaching materials, replacing it with *o* (Starosta, 1999: 19).

Both LSo and USo exhibit grammatical features that set them apart from other contemporary Slavic languages. The LSo verb paradigm still includes the supine found in early Slavic. USo retains a rich system of tenses – present, preterite (also called 'aorist' if the verb is aspectually perfective, 'imperfect' if it is imperfective), future, perfect, and pluperfect; in addition, the literary language and a number of USo dialects retain the iterative preterite tense (formally identical to the conditional mood). The LSo dialects exhibit only one past tense, formed with the auxiliary *byś* 'to be' and the *ł*-participle; literary LSo, in contrast, exhibits all the tenses of USo, artificially (re)created and phonologically adapted. The Sorbian grammatical category of number is expressed as singular, dual, and plural, which is marked both on the noun or pronoun and on the verb. The dual is gradually giving way to the plural in the dialects, often surviving only exceptionally after the quantifier 'two' (USo *dwaj, dwě*) with plural agreement in the verb (*Dwě knize su na blidźe leželi* in lieu of literary USo *Dwě knize stej na blidźe ležałoj* 'Two books lay on the table'). Nouns (substantive and adjective) and pronouns exhibit six cases – nominative, genitive, dative, accusative, instrumental, and locative. A vocative form exists in USo, but only for masculine nouns (*Šćěpan* → *Šćěpano! Šćěpanje!*) and one feminine noun – *mać* (*maći!*) 'mother.'

Sorbian word order is basically SOV (Subject-Object-Verb); however, compound verb tenses and

the clitic status of the auxiliary verbs usually produce a 'bracket construction' like that found in German (so-called *Rahmenkonstruktion*). Sorbian subordinate clauses, in contrast, generally do not imitate the German clause-final placement of finite verbs.

The LSo and the USo dialects are connected by a zone of 'transitional' dialects. Here, LSo lexical and morphophonological features increase and USo ones decrease as one moves from south to north, while USo features increase and LSo ones decrease as one moves from north to south. Although this might suggest a single dialectal continuum (hence, a single Sorbian language), in fact, the degree of mutual intelligibility between LSo and USo proper is perceptibly less than that which exists today between Czech and Slovak.

Sound Change

J J Ohala, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Sound change refers to changes in pronunciation of words or morphemes over time when these changes seem to be attributable to phonetic and phonological causes, not morphological, semantic, or cultural. Pronunciation changes due to the latter factors have other designations, for example, analogical leveling, expressive change due to sound symbolism, spelling pronunciation, and so on (*see* **Sound Symbolism**).

Introduction

Sound change manifests itself in many ways. When reading older literature one becomes aware that certain words are used in rhymes which do not rhyme in 20th-century pronunciation, as, for example, in the following lines from Chaucer's *Knight's Tale:*

> But mercy, lady bright, that knowest weel [='well']
> My thought, and seest what harmes that I feel.

The vowels in these words 'well' and 'feel,' which are [ɛ] and [i], were both [eː] in Chaucer's speech.

Table 1 Cognate words

English	*Italian*
foot [fʊt]	piede [piɛde]
fish [fɪʃ]	pesce [peʃːe]
flat [flæt]	piatto [pjatːo]

Regional dialectal differences must be due to sound change if it is allowed that the same word must have had a uniform pronunciation at some point in the past, for example, presence versus absence of postvocalic *r's* in American versus British English: 'beer' is [bɪɹ] in the USA but [biə] in British Received Pronunciation; similarly, [tʃɛɹ] and [tʃeːə], respectively.

On a much broader scale of 'dialect' differences, an examination of the pronunciation of cognate words in related languages (**Table 1**) also suggests the action of sound change.

Within a given language, morphemes that have a different pronunciation in different morphological contexts (e.g., due to the addition of affixes) give evidence of sound change that occurred in one morphological environment and not another (**Table 2**).

Such changes are said to exhibit 'morphophonemic alternations.'

Finally, some cases of contextually determined variation in the phonetic form of a given phoneme may be a manifestation of sound change, for example, the phoneme /t/ may be realized as [t^h] or as [ʔ] in some American dialects:

(1) trɛntən/ [t^hɹɛ̃ʔn̩]

Table 2 Sound change and morphological context

extreme [ɪkˈstɹim]	extremity [ɪkˈstɹɛmɪti]
repose [ɹɪˈpouz]	repository [ɹɪˈpazɪtɔɹi]
act [ækt]	actual [ækʃəl]

the clitic status of the auxiliary verbs usually produce a 'bracket construction' like that found in German (so-called *Rahmenkonstruktion*). Sorbian subordinate clauses, in contrast, generally do not imitate the German clause-final placement of finite verbs.

The LSo and the USo dialects are connected by a zone of 'transitional' dialects. Here, LSo lexical and morphophonological features increase and USo ones decrease as one moves from south to north, while USo features increase and LSo ones decrease as one moves from north to south. Although this might suggest a single dialectal continuum (hence, a single Sorbian language), in fact, the degree of mutual intelligibility between LSo and USo proper is perceptibly less than that which exists today between Czech and Slovak.

The Importance of Sound Change

A systematic analysis of such evidence of sound change and other forms of language stimulated the development of linguistic science at the beginning of the 19th century and led to the development of the comparative method which permitted the reconstruction of languages' past. On the assumption that sound change must be happening in the 20th century as it has in the past, researchers in language acquisition have been motivated to examine the errors of first and second language learners in order to discern possible parallels between variation that is diachronic (across time) and synchronic (at one point in time).

Physiologists often gain valuable insights into the workings of the healthy body by studying the diseased body. Parallel to this strategy, many researchers regard sound change as a failure of speech communication, that is, a failure to convey a pronunciation norm, and examine it for hints on how speech production and perception – both their physiological and the cognitive aspects – work normally and successfully.

The Literature of Sound Change

The documentation of sound change is enormous and represents one of the great scientific treasures of linguistics. From comparative grammars of language families as well as the vast literature giving descriptions of the phonemic and morphophonemic systems of single languages, it is possible to extract much valuable information on sound change. Unfortunately the digging is hard in this quarry because there is no standardization of terminology or phonological symbols, and the methods of presenting the data vary widely. A few of the more common forms of sound change are reviewed here with examples of each.

Assimilation

This is a change of a speech sound so that it becomes more similar or identical to another adjacent sound:

(2a) 'contend' is derived from the original Latin morphemes
com + *tendere* 'with' + 'stretch, strain'; the final *m* of *com* became *n* by assimilating to the place of the following *t*.

(2b) Italian *notte* comes from the Latin stem *noct-* 'night'; here the c (= [k]) assimilated completely to the following t.

The overwhelming majority of sound changes are assimilations.

Dissimilation

This is a change of a speech sound so that it becomes less like another sound in its vicinity or even disappears entirely, for example, 'pilgrim' comes ultimately from the Latin *peregrīnus* 'foreign' (from which the English 'peregrination' is derived). At some time in its history one of the two original *r's* dissimilated and became *l*. A similar dissimilation relates 'colonel' to original *colonnello* 'column (of soldiers)'; though still spelled with two *l*s, it is pronounced with only one still intact.

Loss of a Sound

This may occur by 'syncope,' 'apocope,' and so on, depending on where in the word the loss occurs; for example, English 'every' is often pronounced as [ɛvɹi] without the medial vowel.

Epenthesis

Epenthesis is the insertion of a sound in the middle of a word, for example, 'arithmetic' is occasionally pronounced with the medial [-θm-] cluster broken up by an inserted schwa [ə]. Some commonly cited cases of epenthesis, for example, the introduced [p] in '*warmth*' [wɔɹmpθ], are best considered cases of assimilation: the [p] is the result of the latter portion of the [m] assimilating to the voicelessness and the elevated velum of the following [θ].

Haplology

This is the loss of one of two successive sounds or sound sequences that are the same or identical, for example, Latin *nutrix* 'nurse' derives from the stem *nutri-* plus the feminine agentive suffix *-trix,* that is, *nutri* + *trix*. One of the two successive identical syllables *tri* was lost. In English the term 'mineralogy' from 'mineral' + *ology* shows haplology with respect to two original successive syllables that were similar but not identical.

Metathesis

This is the transposition of two adjacent sounds. In Old English the source of the word 'wasp' had two varying forms, *wæsp* and *wæps* (as did its Indo-European source **wopsā* and **wospā)*. Similarly, Old English showed variant forms *āscian* and *ācsian* for 'ask.' In some nonstandard dialects of American English this word may be pronounced [æks].

The Process of Sound Change

Among those who study sound change, some of the greatest controversies arise over how and why sound

Table 3 Examples of sound correspondences between Greek and the ancient Germanic languages as covered by Grimm's Law[a]

change takes place. In fact, these disputes have been raging for well over a century, since approximately the neogrammarian revolution in the mid-1870s. No discernible consensus has been reached yet. This short article attempts to convey some of the origins of these disputes and their parameters.

Although speculation about sound change can be found as early as Plato's *Cratylus* (*see* **Plato and His Predecessors**) and was very common throughout the 18th century, it was not until the pioneering work of philologists such as Samuel Gyarmathi (*see* **Gyarmathi, Samuel (1751–1830)**), Rasmus Rask (*see* **Rask, Rasmus Kristian (1787–1832)**), and Jakob Grimm (*see* **Grimm, Jacob Ludwig Carl (1785–1863)**), that a rigorous, systematic study of sound correspondences between cognate words of different languages was undertaken. What has come to be known as Grimm's Law (Grimm, 1822), but was first proposed by Rasmus Rask in 1818 (*see* **Sound Laws**), documented a fairly regular (but not exceptionless) correspondence between Greek voiceless stops and Germanic voiceless fricatives: Greek p, t, k = Germanic f, þ(= [θ]), h(= [x]); Greek voiceless aspirates and Germanic voiced stops, ph, th, kh = b, d, g; Greek voiced stops and Germanic voiceless stops, b, d, g = p, t, k. Some examples are given in Table 3.

Two fundamental assumptions about sound change started the controversy. The first is the fairly commonplace observation that sound change seems not to happen all of a sudden. There has never been a report in history that, 'Today on November 23, 1753, we all ceased pronouncing nasal consonants after vowels and instead made the vowel distinctively nasal.' This leads to the belief that sound change occurs so gradually as to be virtually undetectable.

The second belief arose when Hermann Grassmann (*see* **Grassmann, Hermann Günther (1809–1877)**) and Karl Verner discovered in the 1860s and 1870s rules for two major classes of exceptions to Verner's Law. The impact of this achievement on the philological community of the time cannot be overestimated. For more than four decades philology had accepted, with Grimm, that sound change, whatever its causes, showed the same messiness in application as other aspects of human behavior; there were generalizations to be made but there were inevitably exceptions to these general statements. When Grassmann and Verner showed that even the exceptions (at least a major part of them) could be accounted for by a general rule, they came to believe that sound change operated mechanically and without exception.

As a consequence of sound change applying mechanically and without exception – that is, that all eligible words were affected by it – it was supposed that sound change must progress in a phonetically gradual way. In opposition to the neogrammarians and their view that sound change applied mechanically and without exception were the traditional philologists who insisted that 'each word has its own history' (and thus defies a rule-based account).

The neogrammarians were aware of certain exceptions to the sound changes they discovered, but usually attributed them to psychological and cultural factors (analogy and borrowing from other dialects), which they acknowledged could override the forces that propelled these phonological changes.

In the 20th century, many linguists, the intellectual descendants of the neogrammarians, acknowledge that sound change does not apply without exception, but they still adhere to the notion that it is phonetically gradual and suppose that, for example, the change of the original Indo-European voiceless stops (preserved in classical Greek) changed to the Germanic voiceless fricatives through a process of gradual weakening of the stop closure. (Even if adherence to the doctrine of the exceptionless of sound change has lessened, virtually everyone agrees that the concept was useful heuristically and had a profound effect on the development of linguistics as a rigorous discipline.) On the other hand, there is a renewed acceptance of the traditional philological notion that some or all of the gradualness of sound change – which makes it imperceptible – comes about because a given sound change moves gradually through the lexicon affecting first a few words, then more, and then, possibly, most or all eligible words. This is known as 'lexical diffusion' (Wang, 1977). Furthermore, a sound change can create pronunciation variants which connote social class membership, such that two or more alternate pronunciations are available to a speaker, for example, 'floor' as [flɔ] or [flɔɹ]. Speakers might then fluctuate between one form and another, depending on what sort of social impression they would like to convey. A change in social valence of one variant could allow it to spread gradually at the expense of the other (Labov, 1972). In a pivotal

work, Weinreich *et al.* (1968) advocated, among other things, that a strict distinction be made between how a new pronunciation norm starts vs. how it spreads (from word to word, from speaker to speaker, from one socially marked style of speech to another). Some of the imperceptible gradualness, then, could be in the latter domain (*see also* **Weinreich, Uriel (1926–1967); Labov, William (b. 1927)**).

The Occurrence of Sound Change

Teleology

There have been many theories regarding why sound change takes place. Among the many early speculations on the matter, now discredited, were that the speech organs evolved to necessitate the change, that migrations to different climates (colder regions, windy regions) caused a change in speaking habits. Among the theories still current in the early 1990s, some important divisions remain. One of these is between those that characterize sound change as teleological or purposeful and those that do not. Another is whether or not it is thought that sound change improves a language in some way. Many purposes have been posited behind phonological change, most of them operating unconsciously. Speakers change their pronunciation, it is claimed, to make the act of speaking easier (i.e., to reduce energy expenditure), to make speech clearer for the hearer, to optimize the structure of the language (the grammar) in a variety of ways, and therefore to make it easier to learn, to process, and to remember.

There is no doubt that speakers do vary the amount of energy they put into speaking; the speech of someone who is tired or ill is often poorly articulated and thus harder to understand. It is also a common observation that speakers may change aspects of their pronunciation in anticipation of the needs of the hearer, for example, hearing-impaired or nonnative listeners, or when the environment or the channel utilized, for example, a telephone line, is noisy. However, it is not clear in such cases whether speakers are introducing a new pronunciation norm as opposed to trying to convey the community norm to the best of their ability. Sound change proper should be limited to cases where there is a change in pronunciation norm.

Among the hundreds of ways that speakers are claimed to change the structure of their language in order to optimize it are the following:

1. To make the segment inventory more symmetrical, for example, although Old English had voiced and voiceless stops, it had only voiceless fricatives; Middle English added voiced fricatives, thus making the voiced/voiceless contrast symmetrical among the obstruents.
2. On the assumption that there is something unusual or difficult in making syllables terminating in consonants and especially consonant clusters, any simplification of syllable endings is viewed as a move toward optimization; for example, in North American English 'can't' is often pronounced [kæ̃t]. Many languages spoken in Southeast Asia are known to have undergone remarkable simplifications of the syllable structure, such that by the 20th century some allow only open syllables (those not terminated by a consonant).
3. Languages are said to eliminate phonological contrasts that serve little communicative function, that is, where they are redundant. Thus it has been observed that, of the four nasal vowels of Modern French / ɛ̃ œ̃ ɑ̃ ɔ̃/, /œ̃/ serves to differentiate so few words that it is merging with /ɛ̃/.
4. To simplify the phonological rules governing morphophonemic alternation, for example, around the 9th century French had a rule distinctively nasalizing just the low vowels before a following nasal in the same syllable; by approximately the 13th century this rule had been generalized and thus simplified so that all vowels were nasalized in such an environment.

The problem with analyses such as these and with hundreds of similar ones is that there are so many possible structural features of a language – and occasionally its cultural or political environment – which can be invoked after the fact to 'explain' a given change, that it is often difficult to discern any rigor or discipline in such explanations. It would help if there were statistical studies showing that, in an unbiased sample of languages, those with a given structural feature underwent a certain type of change at a rate greater than chance – change in a direction judged to represent an optimization.

Structural linguistics introduced a new element into speculations about sound change, namely, the underlying structure of a language, which is often posited to be quite distinct from the patterns and elements directly observable. This underlying structure has been viewed as the relations between phonological elements by the Prague School (*see* **Structuralist Phonology: Prague School**), where this type of theorizing about language change started around the 1930s, or as rules of grammar by generative phonology (*see* **Generative Phonology**), and its descendants. In fact, so different are the proposals that different generations of structural linguists have made about a language's underlying structure, that there has never

Table 4 Sanskrit and Prakrit consonant clusters

been a sufficiently stable and long-lived theoretical base on which to launch extensive and wide-ranging research on sound change.

Sound Change and Language Improvement

The claim that sound change brings about an improvement to the language in which it occurs is independent of the claim that there is teleology. As with the evolution of species, many might believe that individuals who survive at the expense of others in the face of environmental pressures are in some way better adapted, but they would still not suggest that there was any teleology, any ultimate goal, in determining the direction of evolution. Invoking principles similar to evolution, Lindblom proposed that there are universal 'environmental' pressures helping to shape the sound systems of language and has presented one of the few rigorous statistical studies in support of this: Lindblom and Maddieson (1988) demonstrated that languages utilized simple segment types (e.g., [p, l, j, a]) before utilizing complex segment types (e.g., [t^{w}, p', k͡p, ã]). Most languages use exclusively simple segment types.

Some have suggested that there is an inherent teleological element in sound change without there being any net benefit from such change; language users implementing change for the sake of change – similar to their change in fashions of clothes and automobiles from one year to the next (Postal, 1968).

Whatever good does come to a language from sound change, it must be localized in time and to a particular domain of language structure, because the evidence suggests that there seems to be no net drift of all human languages toward a common sound pattern. The fate of consonant clusters between Sanskrit (*see* **Sanskrit**) and Modern Hindi (*see* **Hindi**) illustrate this. Sanskrit had a fairly rich set of medial consonant clusters; according to some these are relatively complex phonological structures and liable to change. Prakrit, which developed from Sanskrit, simplified virtually all of these clusters and changed them to geminates (Table 4).

However, in Modern Hindi, a descendant of Sanskrit through Prakrit, there are some very common morphological processes which involve deletion of a interconsonantal schwa [ə], thus giving rise to complex clusters again. In some cases, the form with a cluster came from concatenated morphemes that 20th-century speakers are no longer aware of (Table 5).

While it is certainly not the norm that phonological processes are eventually undone, there seems to be nothing except chance that would prevent it.

Phonetics and Sound Change

Phonetic studies of speech have been applied to issues of sound change for well over a century. Some of the first instrumental phonetic studies were motivated by a desire to explain sound change (e.g., Rousselot's 1891 dissertation). One important finding is common to all these studies; there is a remarkable similarity to the variability found in details of pronunciation – that is, in speech production – by 20th-century speakers and sound changes that took place in centuries past. Some ventured the opinion that the variation found was ongoing sound change, sound change 'on the hoof,' as it were (see Labov, 1981). Some studies have again emphasized the isomorphism between diachronic and synchronic phonetic variation, but have taken a different path after that (Ohala, 1993).

A great deal of variation is found in speech production, it is noted, but this by itself does not constitute sound change, that is, a change in pronunciation norms, because there is evidence from speech perception studies that listeners are usually able to normalize such variant forms and deduce the norm intended by the speaker. For example, the fricative [s] when produced before a rounded vowel like [u] (as in the name 'Sue') is 'colored' a bit to sound less like [s] in other vocalic environments and more like [ʃ]. This change in [s] is caused inadvertently by the assimilation of the lip shape to that of the following vowel [u]. Nevertheless, listeners have no trouble identifying this variant as the phoneme /s/ as long as they detect the /u/ and can 'blame' it for the distortion. Such perceptual normalization must be similar to those operating in perceptions based on other sensory modalities, for example, vision, where viewers successfully normalize for variations in the size, color, and shape of objects viewed from different distances, different ambient lighting, and different angles. However, such phonetically caused perturbations of speech sounds make speech potentially ambiguous to the listener, who has to 'parse' the contextual distortion with the context and not with the given speech segment. Although

usually successful in doing this, listeners occasionally fail. In these cases of parsing errors, listeners perceive the contextually changed segment as it is heard, that is, changed, and this becomes the basis for their subsequent changed pronunciations. Further elaborations of this account of sound change as listeners' parsing errors suggest an explanation for dissimilation.

In contrast to most prior accounts of sound change, this one attributes the change to the listener, not the speaker. The speaker causes the variation, which gives rise to potential ambiguity in the acoustic-auditory signal, but this variation only leads to sound change due to the misapprehension by the listener. The error of the listener is unmotivated, probabilistic, and nonteleological, just like inadvertent errors by medieval scribes or modern typists copying manuscripts or students taking lecture notes. The change is phonetically abrupt, although its subsequent spread, mediated by nonphonetic factors (psychological mechanisms such as analogy and social mechanisms, as discussed above), could be gradual. A further advantage of this account is that it has demonstrated how certain sound changes can be simulated in the laboratory. A disadvantage is that only a relatively small subset of all the types of sound changes that interest historical phonologists have been dealt with in laboratory studies, and thus, a large part of its case is a promissory note.

Trends in Research on Sound Change

Nineteenth-century linguistics *was* historical linguistics. Synchronic studies existed but were usually not at the center of the linguistic community's attention. In the first quarter of the 20th century, structural linguistics changed this, and synchronic studies dominated. In the 1990s it may be said that, with attention being given to sound change by sociolinguistics, by those in language acquisition, by the phonetic sciences, and in the theoretical domain by generative phonology and its heirs, it is again one of the most active and hotly debated research areas in linguistics.

The fact that sound changes is undisputable, but that only a limited set of sound change occurs in the world's languages and many such changes recur across typologically diverse languages has puzzled historical linguists since the advent of the comparative method. Thus, for example, assimilation (1) is commonly found in the world's languages.

(1)	Latin		Italian
	octo	>	otto 'eight'
	noctem	>	notte 'night'
	septem	>	sette 'seven'
	somnus	>	sonno 'sleep, dream'

Equally puzzling is the fact that sound change often displays directionality effects. For example,

usually successful in doing this, listeners occasionally fail. In these cases of parsing errors, listeners perceive the contextually changed segment as it is heard, that is, changed, and this becomes the basis for their subsequent changed pronunciations. Further elaborations of this account of sound change as listeners' parsing errors suggest an explanation for dissimilation.

In contrast to most prior accounts of sound change, this one attributes the change to the listener, not the speaker. The speaker causes the variation, which gives rise to potential ambiguity in the acoustic-auditory signal, but this variation only leads to sound change due to the misapprehension by the listener. The error of the listener is unmotivated, probabilistic, and nonteleological, just like inadvertent errors by medieval scribes or modern typists copying manuscripts or students taking lecture notes. The change is phonetically abrupt, although its subsequent spread, mediated by nonphonetic factors (psychological mechanisms such as analogy and social mechanisms, as discussed above), could be gradual. A further advantage of this account is that it has demonstrated how certain sound changes can be simulated in the laboratory. A disadvantage is that only a relatively small subset of all the types of sound changes that interest historical phonologists have been dealt with in laboratory studies, and thus, a large part of its case is a promissory note.

Sound Change: Phonetics

A Yu, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

The fact that sound changes is undisputable, but that only a limited set of sound change occurs in the world's languages and many such changes recur across typologically diverse languages has puzzled historical linguists since the advent of the comparative method. Thus, for example, assimilation (1) is commonly found in the world's languages.

(1)	Latin		Italian
	octo	>	otto 'eight'
	noctem	>	notte 'night'
	septem	>	sette 'seven'
	somnus	>	sonno 'sleep, dream'

Equally puzzling is the fact that sound change often displays directionality effects. For example,

the majority of assimilation tends to be anticipatory (also referred to as regressive). That is, for a sequence of C_1C_2, it is more likely for C_1 to take on the features of C_2 than vice versa. Even more common are cases of nasal assimilation (2) where a nasal invariably agrees in place of articulation of the following stops, never the preceding one.

(2) English

in-possible	>	i[m]possible
in-tolerable	>	i[n]tolerable
in-compatible	>	i[ŋ]compatible

While one of the crowning achievements of historical linguistics is arguably the discovery of ways to reconstruct the history of languages via the comparative method, the comparative method *per se* has nothing to say about why certain sound changes should be more prevalent than others, nor can it explain why asymmetric directionality effects of sound change exist. The comparative method simply does not require the linguist to understand why languages are structured as they are or behave as they do. Words and their constituent sounds are treated more or less as abstract algebraic entities devoid of physical substance. Thus, the comparative method is analogous to 'a quasi-mathematical operation, involving implicit (and qualitative, not quantitative) estimations of probability of events and what is, in effect, the application of optimization theory' (Ohala, 1993: 237). While some leading historical linguists continue to advocate the view that reconstructed forms are simply parts of a formulae for relating sets of cognates and should not be regarded as representing phonetic structure (Bloomfield, 1914: 274 ff.; Meillet, 1964: 39 ff.), most historical linguists are not completely blind to the need for an explanation for the cause of sound change. For example, it is often implicitly assumed that the posited reconstructed forms and the accompanying sound changes must also be within the bounds of the plausible, where plausibility is generally determined inductively, that is, by what the linguists have previously encountered in other human languages. Historical linguists also often rely on the notion of phonetic plausibility. To this end, historical linguists generally turn to phoneticians for answers.

Phonetics, broadly defined, is the study of the production and perception of speech. There are two main aspects of phonetic research: taxonomic vs. scientific phonetics. Taxonomic phonetics concerns mainly the articulatory aspect of speech. It provides linguistics with the terminology and conceptual framework for describing speech sounds and their natural classes. As an area of research, taxonomic phonetics reached its zenith in the late 19th century through the efforts of phoneticians such as Alexander Melville Bell, Otto Jespersen, Paul Passy, Henry Sweet, and Wilhelm Viëtor. The basic descriptive system has not changed very much since. Unlike taxonomic phonetics, scientific phonetics is a vibrant and growing discipline that focuses on developing methodologies and theories of phonetics toward a better understanding of the working of speech. The marriage between scientific phonetics and historical linguistic research on sound change is what Ohala calls 'experimental historical phonology' (1974).

The union of scientific phonetics and historical linguistics is mainly inspired by two truisms derived from speech research: the infinite variability of speech and the parallelism between such phonetic variation and sound change. That speech shows tremendous variability has been evident to phoneticians as early as Pānini. Equally important, however, is the realization that the variation is often lawfully determined. This restrictiveness of phonetic variation leads many researchers to posit phonetic theories to explain the observed regularities. The application of phonetic theories to explaining sound change is made possible by the second observation, namely, the often observed similarity between phonetic variation and sound changes. For example, previous phonetic research has revealed that the fundamental frequency (F_0) on vowels is often nondistinctively higher following voiceless consonants than voiced ones (e.g., Hombert *et al.*, 1979). Similarly, historical linguists have pointed out that, in East and Southeast Asian languages, a higher tone develops after what had been the voiceless consonants and lower tone after the voiced ones (e.g., Edkins, 1853: 6–54, esp. 47; Maspéro, 1912). These types of similarities are repeatedly observed as instrumental studies and perceptual studies of speech accumulate, which eventually prompted the phonetically minded historical linguists to posit a potential causal relationship between the two (e.g., Haudricourt, 1954). This in turn led phoneticians to apply phonetic theories to the explanation of sound change.

Not all variations constitute sound change, however. On the one hand, the Neogrammarians viewed sound change as the result of microscopic changes in the production of speech, which gives rise to the notion of articulatory drift and the view that sound change is gradual and unperceivable (Bloomfield, 1933). Ohala (1974 et seq.), on the other hand, contends that sound change is mainly perceptually driven and can be demonstrated in the laboratory. In particular, Ohala (1993) argues that variation in perception caused by the confusion of acoustically similar (but sometimes articulatorily different) speech sounds may constitute a (mini-)sound change, but not so for variation in production. Variation in production,

however, may still play an important role in the development of sound change. In particular, when a listener fails to correct the perturbations (e.g., from coarticulation) in the speech signal and takes the signal at face value, his conception of the pronunciation might differ from the intended one. Ohala refers to this as 'hypo-correction.' A canonical example of hypo-correction is the emergence of umlaut in the history of Old English. Umlaut takes place when a back vowel is fronted by a front vowel or a palatal glide in the following syllable. In the case of Old English, the plural suffix *-i* in pre–Old English created a front allophone of the back vowels in the root. The listener hypo-corrected, perhaps due to the failure in detecting the final front vowel (the conditioning factor), and the fronted back vowel subsequently became phonemic when the conditioning environment is lost (e.g., *muːs-i* → *myːs* 'mice').

(3)

Pre-OE	OE	Mod. English
*muːs	muːs	mouse
*foːt	foːt	foot
*toːθ	toːθ	tooth
*gans	goːs	goose
*mann	mann	man

Pre-OE	OE	Mod. English
*muːs-i	myːs	mice
*foːt-i	feːt	feet
*toːθ-i	teːθ	teeth
*gans-i	geːs	geese
*mann0i	menn	men

Examples of hypo-corrective sound change are many, including regressive assimilation (Ohala, 1990), tonogenesis (e.g., a tonal contrast emerges from a historically prior voicing contrast), the development of distinctive nasal vowels (i.e., contextually nasalized vowels become distinctive nasal vowels; ṼN > Ṽ; Beddor *et al.*, 1986), the rise of emergent stops (e.g., *Samson* > *Sampson*; Ohala, 1997), nasal effacement (e.g., Late Latīn *ansa* > Milanese *asa* 'handle, loop, occasion'; Ohala and Buzà, 1995), nasalization-induced lowering (e.g., *fine* [fin] but *fin* [fɛ̃] in French; Beddor *et al.*, 1986) and velar softening (e.g., Lung chow *kjaa*: Po-ai *tʃaa* 'rice seedlings'; Guion, 1998).

Not only do listeners fail to normalize variation in production sometimes, they may also overanalyze and incorrectly attribute an intended phonetic cue as contextual. This mechanism of sound change is referred to as 'hyper-correction.' Hyper-corrective sound changes invariably involve only phonetic features that manifest themselves over fairly long temporal intervals, such as labialization, aspiration, retroflexion, pharyngealization, the voice quality called 'glottalization,' and place of articulation. Only such stretched-out features may encroach on adjacent segments thus creating an ambiguity as to where the feature is distinctive and where fortuitous. A classic type of hyper-correction is dissimilation. Thus, in the history of Sanskrit and Greek, when a root contains two aspirated stops the first dissimilates to an unaspirated stop (i.e., Grassmann's Law). What appears to have happened is that the listener identified only a unique source for the laryngealization, which spanned across multiple syllables in PIE. As a result, aspiration is hyper-correctively eliminated from all aspirated stops except the last.

(4a)	PIE		Sanskrit	
	*b**hu**d**h**yetoy	>	b**u**d**h**yatē	'is awake'
	*b**he**b**h**owd**h**e	>	bubōd**h**a	'was awake'
(4b)	PIE		Greek	
	*p^{h}ak^{h}ús	>	pak^{h}ús	'thick'
	*k^{h}ep^{h}alé:	>	kep^{h}alé:	'head'

Ohala's listener-oriented misperception based explanation of sound change (or what Steriade (2001) refers to as the 'innocent' view of sound change) not only offers great insights into the mechanism of the actuation of sound change in general, but also resolves an important embarrassment for the traditional Neogrammarian view of sound change. The main tenet of the Neogrammarian account of sound change is that sound change is gradual, regular, and exceptionless. Yet it has been repeatedly recognized that there is a class of changes that is sporadic and abrupt (Bloomfield, 1933). These so-called minor sound changes include dissimilation and metathesis. As illustrated above, Ohala's hyper-correction model provides an explanation as to why dissimilatory sound change may take place. Blevins and Garrett (1998, 2004) apply the same mechanism to account for metathesis (Classical Greek *gambrós* > South Italian Greek *grambó* 'son-in-law'). Both types of minor sound changes are the results of the listener failing to correctly identify the source of some long stretched-out phonetic cue. In the case of dissimilation, the listener resolves the ambiguity by reducing the number of conditioning factors, while in the case of metathesis, the listener incorrectly localizes the source of the ambiguity, resulting in an apparent sound transfer.

An important difference between hypo- and hyper-corrective sound changes is in the role of the conditioning environment. In hypo-corrective sound change, the conditioning environment is often lost at the same time as the conditioned change occurs since failure to detect the conditioning environment is a direct cause of the listener failing to implement normalization of a contextual-induced perturbation in the first place. The conditioning environment in a hyper-corrective sound change, on the other hand, crucially may not be lost

at the same time as the conditioned change since the listener must be able to detect the conditioning factor before he may, albeit erroneously, attribute an imagined perturbation to the conditioning environment.

In recent years, a renewed interest in the phonetic explanation of sound change has resulted in several attempts to reevaluate the merits of the listener-oriented misperception view of sound change. For example, Steriade (1999) asserts that the innocent view of sound change fails on two counts. First, patterns of perceptual confusion found in the laboratory do not always match up with attested sound changes. Second, sound change seems to favor outcome that is perceptually optimizing. Note, however, that perceptual confusion is not always bidirectional (e.g., Guion, 1998; Ohala, 1983, 1997), thus it is not at all surprising that sound change may show an asymmetric directionality effect as well. In addition, while the benefit of applying laboratory findings to the explanation of sound change is great, one must exercise great caution in interpreting laboratory results. A variety of factors may influence the outcome of an experiment (e.g., the nature of the stimulus presentation, the method of subject response, etc.). Thus, the discovery of discrepancies between laboratory results and sound change cannot be taken at face value as a definitive failure of the Experiment Historical Phonology program. Another aspect of the listener-oriented model of sound change which has come under increased scrutiny is the listener's role in deciding the direction of a change. Steriade (1999) proposes that linguistic innovations must be channeled in the direction that is least likely to yield blatant departures from the norm through some mechanism of the phonological grammar (e.g., the P-map). Blevins (2004) recognizes a similar gap in Ohala's original model and adds a third mechanism called **Choice**, which refers to the situation where the listener chooses among multiple phonetic representations with distinct phonological representation.

In sum, the cross-pollination of ideas between phonetics and historical linguistics has proved to be beneficial to both disciplines. The study of sound change thus has consistently provided the raw materials for phonological typologies and phonetic explanations while historical linguists, in turn, use these constructs in their hypotheses about sound change trajectories and in their reconstructions.

Sound Laws

J Bourns, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

'Sound law' is a loan translation of the German *Lautgesetz*. This terminology derives from the 19th century, when the elucidation of sound laws was self-consciously equated with discoveries of the natural sciences, such as Boyle's Law or the laws of gravity. A sound law is defined as a descriptive rule formulating the input and output of a usually language-specific sound change under specified conditions. To modern historical linguists the term sound law connotes strict adherence to the regularity principle (i.e., the belief that sound laws have no exceptions), but this was not always the case. For much of the 19th century sound laws were understood merely as general tendencies, mainly due to the many unmotivated exceptions they seemed to admit. But gradually, principled explanations for these exceptions were discovered too, accompanied by significant advances in the study of phonetics. By the 1870s a consensus had emerged in favor of a more rigorous methodology, and after the discovery of Verner's Law (1875; published 1877), the Neogrammarian position on sound change was made explicit: "every change, inasmuch as it happens mechanically, takes place according to *exceptionless laws*" (Osthoff and Brugmann, 1878: xiii; their emphasis). Several notable Indo-European sound laws are discussed below.

An important early breakthrough was Grassmann's Law (1862), discovered by the renowned linguist and mathematician Hermann Grassmann. Early Indo-Europeanists had puzzled over such cognate pairs as Skt. *bhárati* 'bears' : Go. *baíran* 'bear', which showed the usual correspondence Skt. *bh-* : Go. *b-*, and Skt. *bándhati* 'binds' : Go. *bindan* 'bind', which reflected an unexpected Skt. *b-* : Go. *b-*. Internal evidence from Sanskrit posed a similar problem: since the root *dā-* 'give' made a reduplicated present 3 sg. *dádāti* 'gives', from *dhā-* 'put' one would expect **dhádhāti*, but the attested form is *dádhāti*. Grassmann's insight was that in a sequence of two aspirated stops, the first stop lost its aspiration in Sanskrit (*DH...DH* > *D...DH*). Dissimilation of aspirates was also demonstrable for Greek; cf. pres. 3 sg. *títhēsi* 'puts' < pre-Greek **thithḗti* (: Skt. *dádhāti*, to PIE **$d^h eh_1$-* 'put'). Despite the striking similarities displayed by these and other forms, Grassmann's Law is not a common innovation of Indo-Iranian and Greek; rather, the two branches reflect parallel independent developments (cf. Mayrhofer, 1986: 112ff.).

Among the significant discoveries of the 1870s was the Law of Palatals (*Palatalgesetz*), an Indo-Iranian development whose underlying conditions were clarified independently by several scholars. Sanskrit seemed to show an unmotivated alternation of *k* and *c* [tʃ] before *ă*; cf. *kr̥-* 'do', reduplicated 3 sg. perf. *ca-kā́r-a* 'did'. A similar alternation was displayed by *g* and *j* [dʒ] (*gr̥-* 'wake' : *jā-gā́ra* 'is awake'; cf. YAv. *jaγāra*) and *gh* and *j* (*ghas-* 'eat' : *ja-ghā́s-a* 'ate'). Eventually it was shown that *c* and *j* appeared before *ă* when this vocalism corresponded to *ĕ* attested in IE cognates; cf. the enclitic particle Skt. *-ca* 'and' = Lat. *-que* ; Skt. *jāgā́ra* = Gk. 3 sg. perf. *egrḗgore* 'I am awake' (< **egḗgore*); Skt. *jáni-* f. 'woman' : OE *cwene*, OPruss. *genna* 'id'. The only plausible explanation was that early Indo-Iranian still had the vowel **e*, which caused palatalization of (post-*satəm* merger) **k*, **g*, **g^h*, just as *i* had palatalized **k* to *c* [tʃ] in forms such as the Skt. enclitic *cid* (= Lat. *quid* 'what'). Palatalization applied only before the front vowels **ĭ* and **ĕ*, so that *k* was preserved in forms such as Skt. *ka-* 'who', from an earlier **ko-* (< **k^uo-*). Only after palatalization did**ĕ*, **ă*, **ŏ* merge into **ă*, so that PIE **-k^ue-* 'and' and **k^uo-* 'who' appear in Sanskrit as *-ca* and *ka-* respectively. The Law of Palatals elegantly confirmed that **ĕ*, **ă*, **ŏ* were to be reconstructed for Indo-Iranian, and thus also for Proto-Indo-European.

Before the Indo-Iranian merger of mid and low vowels, another sound change is known to have operated in this branch: Brugmann's Law (1876, 1879), whose initial formulation is due to the Indo-Europeanist Karl Brugmann. From comparative evidence it was clear that short *o*-grade of the root was proper to certain Indo-European categories, such as the perfect singular (e.g., Gk. 3 sg. perf. *lé-loip-e* 'left'; *dé-dork-e* 'saw'), and to certain derived stems, such as the causative (e.g., Lat. *moneō* 'warn' < **mon-éi̯e/o-* 'cause to think'). Comparable forms in Sanskrit sometimes displayed a corresponding *-a-*, as in 3 sg. perf. *da-dárś-a* 'saw' (= Gk. *dédorke*), but elsewhere showed an unexplained long *-ā-* instead, as in 3 sg. perf. *cakā́ra* 'did' and causative 3 sg. pres. *māráyati* 'kills' (< **more̯i̯e/o-* 'cause to die'). Brugmann hypothesized that in the development of Indo-Iranian, PIE **o* was lengthened to **ō* in *open syllables* (syllables ending in a vowel), and that thereafter **ō* merged with *ā*, thus PIE**k^ue.k^uó.re* > *cakā́ra*, **mo.ré.i̯e.ti* > *māráyati*, but **de.dór.ḱe* > *dadárśa*. Important further discoveries eliminated a number of apparent exceptions to this rule, such as 1 sg. perf. *cakára* 'I did' < **k^uek^uórh$_2$e*, causative 3 sg. pres. *janáyati*

'begets, bears' < *ĝonh$_1$éi̯eti, where the former presence of laryngeals was shown to have blocked application of Brugmann's Law. The scope of this law has been much debated since Brugmann's time; a widely accepted version restricts the rule to lengthening of PIE *o in open syllables before the resonants *r, *l *m, *n, *i̯, *u̯, and the sibiliant *s, though other formulations are used as well.

Evidence for Bartholomae's Law (1882) is adduced mainly from Indo-Iranian, though this development is often attributed to PIE. It was observed by the renowned Iranist Christian Bartholomae that when a morpheme such as the past participle suffix *-tá-* was added to Sanskrit roots ending in a voiced aspirate, aspiration spread to the end of the cluster and the voiceless consonant became voiced; cf. *yudh-* 'fight' + *-tá-* → *yuddhá-* 'fought'; *labh-* 'grasp' : *labdhá-* 'grasped'. The assimilation rule *$D^hT > DD^h$ may also be seen in formations where Grassmann's Law has applied, e.g., *budh-* 'awaken' (< PIE *b^hud^h-) : *buddhá-* 'awakened'; *dah-* 'burn' (< PIE *d^heg^{uh}-) : *dagdhá-* 'burned'. Bartholomae's Law is evident in Avestan as well: IIr. *augh- 'speak solemnly' + 3 sg. middle ending *-ta* > Gathic Av. *aogədā* 'he spoke'. The existence of Indo-European suffix doublets such as *-tro-/*-d^hro-, *-tlo-/*-d^hlo-,*-tmo-/*-d^hmo- is thought to point to the earlier operation of Bartholomae's Law in PIE, e.g., *(-D^h)-tlo- → *(-D)-d^hlo-.

In recent decades further sound laws have been discovered due to the clarification of the PIE laryngeal theory. Significant for Greek is Rix's Law (Helmut Rix, 1970), which illuminates this language's treatment of word-initial PIE laryngeals before a syllabic liquid or nasal. Rix demonstrated that in the development of Greek an inherited sequence of the structure *HR̥C-* underwent resyllabification, with the result that PIE */h$_1$R̥C-/ > Gk. eRC- PIE */h$_2$R̥C-/ > Gk. aRC-, and PIE */h$_3$R̥C-/ > Gk. oRC-. Examples include PIE */h$_1$r̥sk̂e-/ 'go' > Gk. *érkhomai* 'I go' (cf. Skt. *r̥cháti* 'goes'); */h$_2$r̥ĝ-rók̂ / 'bright' > Gk. *argrós > argós* (cf. Skt. *r̥jrá-*); */h$_2$r̥t/ĝók̂/ 'bear' > Gk. *árktos* (cf. Skt. *r̥ksa-*); */h$_3$n̥bh-l̥-/ 'navel' > Gk. *omphalós* (cf. OIr. *imbliu*). Cognate with this last example are Lat. *umbilīcus* 'navel, projection, center' and *umbo* 'boss, center of a shield'. These forms are seen as evidence for Rix's Law in Latin, where normally syllabic *m̥, *n̥ > *em*, *en;* cf. also Lat. *unguis* 'nail' < */h$_3$n̥g^h-u-/ (to Gk. *ónuks* 'nail' < */h$_3$n̥g^h-/); Lat. *amb* 'around, about' < */h$_2$m̥b^h-/ (to Gk. *amphí*, Skt. *abhí*, OHG *umbi* 'around').

The reconstruction of PIE laryngeals has helped solve a long-standing problem of Germanic as well. *Verschärfung* ('hardening') refers to the process by which PIE *-i̯- and *-u̯- developed to PGmc *-jj-* and *-ww-*, yielding *-ddj-*, *-ggw-* in Gothic and *-ggj-*, *-ggv-* in Old Icelandic; cf. Go. *waddjus*, OIcel. *veggr* 'wall' < PGmc *wajju-*; Go. *glaggwuba* 'carefully' beside OIcel. *glǫggr* 'sharp-minded', OE *glēaw* 'sharp-sighted, keen', OS OHG *glau* 'smart' < PGmc *glawwa-*. A comparison of IE cognates reveals that most Verschärfung cases may be traced to root-forms ending in a laryngeal, e.g., the PIE root *u̯ei̯h$_1$- 'wind, twist' underlies Skt. *váyati* 'weaves', past ptcp. *vītá-* (< *u̯iH-ta-*); cognate is Go. *waddjus* 'wall' (< PGmc *wajju-*), ultimately from a root noun *u̯oi̯h$_1$-/ *u̯(e)i̯h$_1$- 'wickerwork'. As shown by JayJasanoff (1978), the development of PGmc *jj* and *-ww-* in such forms was probably triggered by the loss of an intervocalic laryngeal, with the resulting hiatus filled by a euphonic glide. This new sequence yielded geminate glides in Proto-Germanic, which then developed independently to *-ddj-*, *-ggw-* in Gothic and *-ggj-*, *-ggv-* in Old Icelandic. Compare the development of the Germanic verb for 'hew', whose IE cognates include Lith. *káuti* 'strike' and OCS *kovati* 'forge': pre-PGmc *kau̯h$_2$-e/o > *χau'a-* (reflecting hiatus due to laryngeal loss) > *χauwa-* (hiatus filled by euphonic glide) > PGmc *χawwa-* (reinterpretation of *-uw-* as phonological geminate) > OIcel. *hǫggva*, OE *hēawan*, OHG *houwan* 'hew, strike'.

Sound Symbolism

I E Reay

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 8, pp. 4064–4065, © 1994, Elsevier Ltd.

Sound symbolism is said to be present when a speech sound seems to correlate with an object in the real world. The correlation may take the form of 'onomatopoeia' or 'mimesis,' where a sound originating from an animate or inanimate source is reproduced more or less accurately by the human articulatory organs as a lexical item.

The correlation may also be prompted by a vague feeling of 'aptness' within a given speech community. For example, words with initial *tw*-may be felt to express the concept of plucking or tweaking in English: *tweak, twang, twinge, twist, twiddle*. Such a shared cultural response to the sound and meaning of words is known as 'phonesthesia,' the above list of words being 'phonesthemes.'

In general, sound symbolism is culturally bound, and onomatopoeic and synesthetic elements do not pass across unrelated languages.

Although sound symbolism is generally accepted as a phenomenon of language, the actual ratio of words in English that are expressed by sound symbolic elements is disputed by linguists. Some feel that language is mainly arbitrary and that sound symbolism is a mere fringe phenomenon (Saussure); others aver that language is inherently sound symbolic and always striving to equate sound with sense (Bolinger, 1965; Wescott, 1980). A similar question about whether the English language is growing more or less sound symbolic or whether it maintains a 'steady state' equally remains unanswerable.

The term 'iconism' is sometimes used to express the tendency for language to equate sound and meaning (Wescott, 1971). Linguistic iconism is therefore an alternative term for sound symbolism. The word 'icon' was first used with regard to language by the American philosopher C. S. Peirce (1839–1914). Often in linguistic debate, the arbitrary nature of language is called 'symbolism' and is opposed to the nonarbitrary iconism or sound symbolism. Thus, the general term 'sound symbolism' is a little unfortunate, but is widely used and recognized by linguists to represent the nonarbitrary quality of language.

Onomatopoeia

Onomatopoeia or mimesis is the function whereby the sound of a word mimics a sound occurring in the real world (e.g., *miaow, hiccup, plop, cluck, burp, atishoo*, etc.). An onomatopoeic word often denotes the source of the sound (e.g., *cuckoo, crow* [originally *craw*, which echoes *caw*], *kazoo, hurdy-gurdy*).

None of these words are perfect copies of the sounds as they exist in the world, as human speech mechanisms have their limitations. This can be clearly seen when observing the spectrogram of a domestic cat miaowing and that of an English-speaker saying /mjiaʊ/: The two spectrograms show completely different patterns.

Reduplicatives

Reduplicative words are often onomatopoeic and express an ongoing repetitive sound. Reduplicatives fall into three groups:

1. words that are based on rhyming combinations: *clap-trap, hodge-podge, bow-wow, hubble-bubble*
2. words that are true repetitions and often denote the source of the sound, especially in child language: *quack-quack, ba-ba, moo-moo, chuff-chuff, puff-puff*
3. words with vowel alternation, also known as 'apophony' or 'vowel gradation': *chitter-chatter, tittle-tattle, ding-dong, pitter-patter, tick-tock*.

In the great majority of this type of reduplicative, the initial vowel of the first word is the high front vowel /ɪ/, whereas the second element displays a lower vowel /a/ or /ɒ/.

All three types of reduplicatives occasionally have examples with an extra linking syllable: *ding-a-ling*; *clinkety-clink*; *clippety-clop*.

Phonesthemes

J. R. Firth coined the term 'phonestheme' (adjective 'phonesthetic') to describe certain phonological features that are associated with social and personal attitudes within a speech community. (Many modern linguists deviated from Firth's adjective phonesthetic; (Bolinger 'phonesthematic'; Wescott 'phonesthemic.') Such social and personal attitudes are formed through recurring experiences in certain contexts.

> 'The validity of a phonestheme is, in the first instance, contextual only: if it fits the meaning of the word in which it occurs, it reinforces the meaning, and conversely, the more words in which this occurs, the more its own meaning is strengthened' (Samuels, 1972: 46).

This mutual strengthening means that phonesthetic groups may grow larger through time, either through

Figure 1 This figure illustrates a phonestheme network that may be extended indefinitely. Reading from left to right, the following phonesthemes may be identified: Initial phonesthemes: *sc-* 'one who shirks work or duty,' *sc-* 'light movement,' *sl-* 'sliding movement,' *du*-dull, defective,' *du-* 'dull, stupid,' *cl-* 'clinging action,' *sw-* 'movement through air.' Final phonesthemes: *-ip* 'sudden, quick movement or sound,' *-ump* 'dull, unattractive,' *-ump* 'rounded object or collection of objects,' *-oop* 'parabolic shape or movement,' *-ing* 'resonant sound.' Vowel phonesthemes: i /ɪ/ 'swiftness' *slip, nip, i* /ɪ/ 'high pitch' *ring, sing, u* /ʌ/ 'dull, dud' *dull, dud.*

initial phonesthetic clusters (alliteration) or final clusters (rhyme) (see below).

Initial Phonesthemes

Initial phonesthemes may be divided into three groups:

Initial Single Consonant C

- *d*-foolish, dull: *daft, dead, dense, dim, dithery, dizzy, dopey, dotty, dozey, drippy, droopy, dud, duff, dull, dumb, dunce, dupe*

The pejorative force of initial *du-* /dʌ/ can be clearly seen from the above list (see also **Figure 1**).

Initial Double Consonant CC This is the most common type of phonestheme in English, and of this type, *sl*-is perhaps the most highly phonesthetic group of all, with few words that cannot be fitted into one of the phonesthetic categories listed below.

There are two distinct phonesthemes in this *sl*-group:

1. *sl*-attack – physical or verbal: *slag, slam, slander, slang, slap, slash, slate, slaughter, slay, slight, sling, slog, slug, slosh, slur*
2. *sl*-sliding movement: *slalom, sledge, sleigh, slick, slide, slip, slither, sloop, slope, slouch, slump* (see **Figure 1**).

- *sl* – slimy wet substances: *slime, slop, slosh, sludge, slurry, slush*
- *sl* – eject or add water: *slake, slobber, sluice, slurp*
- *sl* – indolence, carelessness: *slack, slattern, sleazy, slob, slut*
- *sl*–cunning, crafty: *sleuth, slippery* (customer), *slick* (operator), *sly.*

A final small group may be included: *sl*-slim, thin: *slender, slim, slit, sliver*

When adjusted in this way, it turns out that 91% of English words beginning with *sl-* are phonesthetic.

A less obvious phonestheme is *sw-* movement through air or water: *sway, sweep, swerve, swim, swing, swish, swivel, swoosh*. To this list could be added *swan, swallow*, and *swift*, as these birds move swiftly through air or water.

Dwight Bolinger has noted the interesting fact that the initial *st*-phonestheme may express the two opposed concepts of movement and arrest (1965):

- *st*-movement: *stamp, stampede, start, startle, step, stimulate, sting, stir, stomp, stray, stream, stride, stroll, strut*
- *st*-arrest: *stall, stay, steady, stick, stop, stub, stump*.

Subcategories of these two groups may be identified as follows:

- *st*-movement – attacking action: *stab, stamp, stampede, stick, sting, storm, strafe, strike, stun*
- *st*-arrest – reliable, steadfast: *stable, stalwart, staunch, steadfast, steady, stolid, stout, strong, sturdy*
- *st*-arrest – implacable, rigid: *starchy, steely, stern, stiff-necked, strait-laced, strict, stubborn, stuffy.*

Initial Treble Consonant CCC-:

- *spr*-spring, spread out: *sprawl, spray, spread, sprinkle, sprig, spring, sprout*
- *spr*-spirited, energetic: *sprightly, spry, springy, spree, sprint*
- *str*-effort against obstruction: *strain, stress, stretch, strive, struggle* (see below)
- *str*-stretch out, scatter: *straddle, straggle, strand, stray, stream, stretch, strew, string* (out).

It is interesting to note that the two categories of both spr- and str- phonesthemes express the similar concepts of 'energy' and 'striving,' and 'stretching or spreading out.' This could lend some weight to the argument that it is the difficulty of articulation of these initial consonant clusters that helps reflect the semantics of this group of words (see below). With these groups could be compared *scr*-eke out, struggle to exist: *scrabble, scrape, scratch, scrimp, scrounge*. The notion of struggling to survive by *scrimping and scraping* is common in English, and this collocation reflects the 'vowel alternation' or 'apophony' seen in so many English reduplicatives.

Final Phonesthemes

As with initial phonesthemes, three groups may be identified:

Final Vowel Plus Consonant V+C Final plosives function as phonesthemes, expressing contact between two objects or surfaces. A voiceless plosive such as *-p* denotes actions that strike and then glide off: *slap, clap, rap, tap, flap, lap*. Voiced plosives, however, denote striking that stops in or on something: *dab, grab, stab, nab, daub* (Bolinger, 1965).

The *sw-* group provides a useful illustration of how a final plosive suggests contact. *Sway, swerve, swim, swing* all express movement with no final contact, whereas *swap, swat, sweep, swipe, swoop* suggest movement with final contact. The verb *swap* originally referred to the slapping together or swapping of hands over a bargain struck; hence, the collocation to *strike* a bargain. In this sense of the verb *swap*, the original phonesthetic force has been lost as no one now considers the original meaning. There is, however, a current dialectal verb, *swap* (Sussex), meaning 'to cut down long grass with a swap-hook.'

Final voiceless plosives may also express a sudden sound: *clack, click, cluck, crack, tick, whack*. A duller, more muffled sound may be denoted by a voiced plosive: *pad* (along), *thud*.

Another way in which the plosives /d/ and /t/ are used phonesthetically is to represent, respectively, a relatively gradual and a relatively abrupt process in English past tense endings:

> '*Spilled* seems more natural than *spilt* in *The water spilled drop by drop over the rim*; *spilt* more natural than *spilled* in *The milk spilt all over the floor when she dropped the pitcher*' (Bolinger and Sears, 1981: 130)

The voiced sound of /d/ is less abrupt than the voiceless sound of /t/ in: *jolt, volt, bolt, halt, dealt* (a blow).

The velar nasal /ŋ/ in final position denotes a resonant, long-lasting sound: *bang, bong, clang, ding, dong, gong, ping, ring, sing, song, ting, twang*. This final nasal sound also illustrates the 'synesthetic' qualities of many phonesthemes, namely, the ability to denote nonauditory experience. 'Synesthesia' or 'cross-modal association' is clearly present in several words with final *-ng*. *Cling* suggests the physical hanging onto something for a space of time, whereas *hang* whereas can refer to physical suspension, such as a man hanging on a gibbet or merely hanging around (i.e., being physically present for a space of time). *Tang* suggests a strong taste that remains or hangs around in the mouth; a *pong* remains in the nose, and a *pang*, although sudden, may remain physically in the body or metaphorically in the heart. In fact, the final *-ng* phonestheme represents all the different senses, but, as one would expect, expresses no action or movement apart from the verb *swing*, where the movement nevertheless is not abrupt but takes some time, thus fitting in with the *-ng* group.

Final Vowel Plus Two Consonants V+CC This group of final phonesthemes ends with two written consonants that are realized as one speech sound (e.g., *-ash* /aʃ/), with the preceding vowel here functioning as an integral part of the phonestheme.

The group *-ash* /aʃ/ denotes impact (sometimes violent) with a giving surface of some kind: *bash, clash, crash, dash* (*against*), *gnash, hash, lash, mash, plash, smash, splash, trash, thrash*. The final fricative sound in this group suggests contact with a soft or giving surface; thus, *swish* represents the movement through air of a curtain, lady's dress, an animal's tail, a whip etc., or movement through water of a boat or a

fish. A similar effect may be seen in *swoosh*; albeit here, the movement seems a little more violent (e.g., the swoosh of a rocket taking off). Finally, the *swash* blow in fencing, delivered downward to the body, travels through the air and then comes in contact with the giving surface of *flesh*.

Such final fricatives contrast with final plosives, which suggest contact with a hard surface: *tap, knock, whack, pat, skid, thud*. There seems to be an underlying pattern in the use of final plosives and fricatives to suggest contact with a hard or soft, unobstructive surface in *skid, skim, ski*. Here *skid* suggests violent contact with a hard surface, *skim* suggests movement across a surface without friction or contact with a soft surface such as skimming the top of the milk, whereas *ski* with no final consonant is paralleled by *fly*, whereas movement is completely free and unimpeded without contact of any sort (compare: *swipe, swish/swoosh, sway*).

Another group has two final consonants that are realized as two separate speech sounds, and often as in the group above, the preceding vowel is an integral part of the phonestheme. A phonestheme of this type is *-ump*, which expresses two distinct concepts:

- *-ump* /ʌmp/, clumsy unattractive: *bump*(*kin*), *chump, dump, frump, grump*(*y*)
- *-ump* /ʌmp/ a rounded object or collection of objects: *bump, clump, dump, slump, stump* (see Figure 1).

Final Vowel Plus Three Consonants V + CCC In this group, all three consonants are realized as three speech sounds as *-umble* /ʌmbl/, repeated awkward movements: *bumble, fumble, stumble, tumble*. Once again, the pejorative force of /ʌ/ can be seen as in *-ump* above.

Vowel Phonesthemes (Phonetic Symbolism)

As far back as 1922, Otto Jespersen observed that the high, front vowel /i/ has a diminutive force as in *wee, teeny*, whereas the low back vowel /ɑ/ has an augmentative force as in *vast, large*. The diminutive suffixes *-ie*, *-kin*, and *-ling* also use the /i/ phonestheme. Jespersen also noted that /i/ is expressive of a very short time, as in the phrase *in a jiff, jiffy* as well as *quick, swift, vivid, blitz* (1922: 402).

Subsequently in 1929 Edward Sapir coined the term 'phonetic symbolism' to describe the fact that some words 'sound bigger' than others. His innovatory experiment to test subjects' reactions to a pair of nonsense syllables *mil, mal* 'table' for the concepts 'small,' 'large,' has led to a whole series of similar experiments. These later experiments have investigated many other synesthetic or cross-modal associations expressed by the vowels /i/ /ɑ/. Fischer–Jørgensen (1967) added to Sapir's original experiment the following set of associations using CVC monosyllables as Sapir had done: bright/dark, angular/round, hard/soft, light/heavy, tense/relaxed, tight/loose, narrow/broad, and thin/thick. Fischer-Jørgensen gained positive correlations in all these areas of perception, and Tarte and Barritt (1971) also saw a 'striking orderliness' in results using elliptical or triangular figures of different size to match with CVC monosyllables, identical apart from the vowel /i/ /ɑ/. The conclusion drawn from these and other similar experiments is that certain vowel sounds tend to group in semantic clusters, and in the case of the high front vowel /i/ and lower back vowels /ɑ/ /ɔ/, these clusters are in definite opposition (French, 1972).

When looking at the lexicon of English, certainly the high front vowels /i/ and /ɪ/ are very marked in their ability to express the concept of 'smallness,' especially small objects. Gulliver was placed among the *wee* men of *Lilliput* and would have been regarded as a *pipsqueak* among the giants of Brobdingnag. This vowel has also assisted meaning change; for example, *pittance*, a scanty allowance, originally denoted any pious donation whether great or small, and a *miniature*, originally an image painted with minium or vermilion, has come to mean a small painting. The word *minuscule* is often spelt *miniscule* under the influence of the *mini*-prefix. It is noticeable that many musical instruments that are capable of playing low-pitched notes have English names containing half-open or open vowels: *organ*, *horn, trombone, double bass, harp, tuba, cor anglais*, (*kettle-*) *drum, marimba*; other instruments characterized by high pitch have names containing close or half-close monophthongs or diphthongs with close end points: *violin, fiddle, fife, flute, cymbals, piccolo, tin whistle*.

Phonestheme Networks

Phonestheme groups have a tendency to ramify in networks throughout the language, forming what Bolinger called 'word constellations.' Such constellations consist of groups of words sharing similar meanings and linked by alliteration (shared initial phonestheme clusters) and rhyme (shared final phonestheme clusters). The ramifying network of phonesthetic words illustrated in Figure 1 could be extended indefinitely (see also Bolinger, 1965).

Wales (1990), using tables compiled by the phonetician A. C. Gimson, identified sequences of vowels and consonants in English that have significant phonesthetic or expressive possibilities. Many such sequences have their roots in Germanic and Old English; for example, /sk/ suggesting fris*k*y movement

in Middle English: *skip* (probably from Old Norse), *skim* (from Old French), *scuttle* (dialectal), *skid* (17th century), *scurry* (19th century), *scoot* (19th century U.S.), *skedaddle* (19th century), (Wales, 1990; see also Figure 1).

This *sc- sk-* group illustrates the point that a phonestheme group can develop from a phonestheme nucleus of Old English roots, which have perennially attracted new words through borrowing, blending, alliteration, and rhyme, and the perceived similarity of meaning. Professor Michael Samuels put this more simply: "A phonestheme may grow from minor coincidental identification between a few roots to much larger patterns" (Samuels, 1972: 47). The words *scamper, skedaddle, scoundrel, scallywag, skulk, scrimshank, skive* are all labeled 'etymology unknown' or 'etymology uncertain' in modern dictionaries. They all share in common the meaning 'swift, light movement,' thus associating them with the initial *sc- sk-* group. There is, however, a further association of 'swift, light movement away from one's responsibilities and duties'; hence, the pejorative sense of these words, a sense that is even present in the original *skip* 'to skip one's duty' (see Figure 1). These additions illustrate well the 'larger patterns' that such a phonestheme may acquire through time, and perhaps *scab*, 'a disloyal trade unionist,' could be added here also.

Examples of borrowing are Anglo–Indian *cushy* 'comfortable, soft,' German *strafe* 'to punish,' Norwegian *slalom* 'a downhill ski race.' All these words fit into phonesthetic groups: *cushy, cu-* /kʊ/- /kʌ/- 'comfortable, soft, cuddly, cushion'; *strafe st-* 'attack': *slalom sl-* 'sliding movement.' To these may be added Greek *Stoic* 'a follower of the philosopher Zeno,' for this word could also fit into *st-* 'reliable, steadfast.' This latter example illustrates the unimportance of original etymology, as *Stoic* derives from Greek *stoa* 'a porch,' this being the porch under which Zeno sat when teaching his disciples.

Blends

Over the centuries, 'blending' has played a significant role in the production of phonesthetic and slang neologisms. This process whereby words are linked together by similarities of initial and final clusters has probably been underestimated (Jespersen, 1922). Such blends motivated by phonesthetic forces are drawn into phonestheme networks.

- *bat* (1205) × *mash* (1000) > *bash* (1641)
- *clap* (1375) × *crash* (1400) > *clash* (1500)
- *smack* (1746) × *mash* (1000) > *smash* (1778)

The above dates show the earliest occurrence recorded in the OED.

Phonesthetic blends account for many words recorded in both the OED and modern dictionaries as of 'uncertain, obscure, or unknown origin.' The highly phonesthetic *sl-* group records *slaister* 'to plaster in a wet or dirty manner' (of obscure origin); *sleer* 'to look askance' (of obscure origin); *slodge* 'to trail or drag the feet' (imitative?); *slouse* 'to wash with a copious supply of water' (suggested by *sluice* and *souse*?). Apart from *slaister*, the above words are now obsolete even in dialect. They do illustrate, however, what Bolinger termed the 'iconic drive' in language to make the sound conform to sense. The above blends can be analyzed by attaching them to the appropriate *sl-* phonestheme:

- *slaister*: *plaster* + *sl-*, 'eject or add water' + *sl-* 'indolence, carelessness'
- *sleer*: *leer* + *sl-*, 'sliding movement'
- *slodge*: *trudge* + *sl-*, 'indolence, carelessness,' + *sl-* 'sliding movement'
- *slouse*: *souse* + *sl-*, 'eject or add water.'

Universality of Sound Symbolism

It is generally acknowledged by linguists that certain forms of sound symbolism function across different language groups. In most cases, the evidence for sound symbolism crossing related languages is more readily available than that for unrelated languages.

Onomatopoeia

Certain words that mimic animal or bird sounds, although not absolutely identical, do show marked similarities across language groups. The sound of the cuckoo is perceived and transcribed somewhat similarly across different languages: English *cuckoo*, Fre *coucou*, Sp *cuclillo*, Italian *cuculo*, Rumanian *cucu*, German *Kuckuck*, Greek *kókkyx*, Ru *kukushka*; non-Indo–European: Hu *kakuk*, Finnish *käki*. Showing a similar marked resemblance is the sound of a cock crowing: English *cock-a-doodle-doo*, Swe *kuckeliku*, Dan *kykeliky*, Fre *cocorico*, Sp *coquelico*. Similar to English too are the words for noises made by an Italian sheep *bè*, a Turkish duck *vakvak*, and a French turkey *glouglou*.

Human sounds too can have similar transcriptions, (e.g., the /r/ in snore: German *schnarchen*, Du *snorken*, Latin *stertere*, Fre *ronfler*, Sp *roncar*, Ru *šeptat'*, Hu *horkolni*, Turkish *horlamak*). Similarly the /s/ in whisper: German *wispern* and *flüstern*, Norw *hviske*, Latin *susurrāe*, Fre *chuchoter*, Sp *cuchichear*, Ru *šeptat*, Hu *súgni, susogni, suttogni*.

Many sounds, however, are transcribed quite differently as the following set of reduplicatives show:

- The sound of a dog barking: English *bow-wow*, Ira *amh-amh*, Serb–Cr *av-av*
- The sound of a bell ringing: English *ding-dong*, German *bim-bam*, He *tsil-tsul*
- The sound of a door banging: English *bang*, Du *plof*, Ru *bats*.

A similarity here lies in the reduplicative structure and the initial plosives in the case of a bell ringing and a door banging, but apart from this the words are quite different.

Phonesthemes

Sets of phonesthemes cluster together forming groups in specific semantic fields, and as these groups are formed by social and personal attitudes, they vary from language to language. Experiments to investigate whether phonesthemes occur across languages have been very inconclusive. Equally, experiments to investigate the narrower area of vowel phonesthemes or phonetic symbolism have also come to the conclusion that the connotations of these sounds are not shared among language groups.

However it has been noted that, in a tonal language such as Cantonese, high pitch connotes smallness, and the /i/ phonestheme has a high pitched second formant. In addition, diminutives expressed by the /i/ suffix do seem to pass across language communities: English *-y*, *-ie*, *-kin*, *-ling*; Du *-ie*, *-je*; Greek *-i-*; Goth *-ein*; Swiss German *-li*; Italian *-ino*; Sp *-ico*, *-ito*, *-illo*. It has also been suggested that the words *mama* and *papa* may work as partial universals, and this is perhaps a case of /ɑ/ expressing the concepts of 'warm, round, soft.' Woodworth (1991) examined deictic elements in 26 languages for evidence of the /i/ *near* /ɑ/ *far* dichotomy. Her results showed a high correlation in some unrelated languages in this group, and she concluded that this forms some basis for a relation between the vowel quality of proximal and distal forms and their meaning language universally.

The enormous number of world languages means that research into possibilities of even partial universals in sound symbolism must necessarily proceed at a slow pace. So far, no true universals in sound symbolism have been found, although, as stated above, near universal elements like *mama papa* and certain deictic elements have been cited.

Sound Symbolism in Poetry and Literature

Sound symbolism always has been pervasive in poetry. When Alexander Pope said that in poetry, "the sound must be seen to echo the sense," he was stating a poetic commonplace.

Sound symbolism may be used to effect a certain intonation when reading a line of poetry either aloud or silently, and often the enforced intonation will echo the sense of the line. The following lines from Pope's *An Essay on Criticism* (1711) illustrate the above point:

> When Ajax strives some Rock's vast weight to throw
> The Line too labours, and the Words move slow.

The reader is forced to slow down when coming to these lines for a number of reasons, thus echoing the difficulty and slowness of the task described. The difficulty of transition from one identical (or similar) sound to the next makes the first line very obstructive. 'Ajax-strives,' 'strives-some,' 'weight-to' are syllables in poetry as opposed to everyday discourse and so must be pronounced without the elision of casual speech. Thus, enforced pauses between these syllables slow down the line (Epstein, 1978).

The word 'strives' forms part of the phonestheme group *str-*, difficulty or obstruction: *strain*, *straggle*, *stretch*, *struggle*, *stricture*, (and with prefix) *restrict*, *constrict*, *obstruct*.

The combination of these sound symbolic factors enables Pope to produce a couplet that is a verbal icon of the process in question.

Another example of Pope's exploitation of the 'public' performance of poetry, which precludes everyday elision also appears in *An Essay on Criticism*:

> And ten low Words oft creep in one dúll Liṅe

Enforced pauses must take place between 'And-ten,' 'low–Words,' and 'dull-Line,' whereas *dull* carrying as it does the *du-* /d/- 'dull' phonestheme must be stressed in a reading of this line.

James Joyce in *Ulysses* used nonlexical onomatopoeia, (e.g., *Pprrffrrppff* to represent the sound of farting, and *krandlkrankran* to express the sound of a clanking Dublin tram; Attridge, 1984). He also used lexical onomatopoeia and phonesthemes in such a way that the words work both onomatopoeically and phonesthetically, as well as semantically drawing other words by means of alliteration and rhyme into the imitative network: 'Clock clacked,' 'jingle-a--tinkle jaunted,' 'One rapped on a door, one tapped with a knock.'

Similarly, he evoked music: 'Brightly the keys, all twinkling, linked, all harpsichording.' Twinkling associates with tinkling, thus linking sight and sound; twinkling also reinforces brightly, and the words *twinkling* and *linked* contain the /I/ phonestheme the has connotations of small, bright, and

light (in weight). Thus, the high-pitched sound of the playing is phonesthetically suggested by the rhyming /Iŋk/ sound, which not only suggests tinkling but possibly also the *pink-a-pink* of a piano.

Secondary Sound Symbolism

The functions usually recognized as primary sound symbolism are onomatopoeia and phonesthemes including vowel phonesthemes otherwise known as phonetic symbolism. There are, however, forms of secondary sound symbolism that work within language communities. Four of these involve allusion to words not actually uttered by the speaker, whereas a fifth and a sixth harness, respectively, intonation and facial expression in appropriate ways.

Spoonerisms

These slips of the tongue are attributed to the Reverend William Spooner (1844–1930), who is reputed to have said, "May I sew you to another sheet?" for "May I show you to another seat?" The *metathesis* or reversal of *s* and *sh* produced a sentence that has no nonsense words and is grammatically correct, but comical in the given context of utterance. He also said "beery wenches" for "weary benches," and no doubt many of his 'mistaken' spoonerisms were created for comic effect. Invented spoonerisms are a form of witticism such as that produced by the poet Algernon Swinburne who wrote to his female cousin "By Merest Dozen" for "My Dearest Cousin" (Jakobson and Waugh, 1979). Another witty spoonerism using a double metathesis is 'Wait till the nun signs Shelley' for 'Wait till the sun shines Nelly.' Most spoonerisms work on the metathesis of one or more initial sounds, but occasionally a blend may be used as in 'We all jumped on him like a toad of bricks,' *toad* here being a blend of *ton/load*.

Rhyming Slang

Rhyming slang is found in Australia and the United States, as well as in London as the famous Cockney rhyming slang. There is a sense in which rhyming slang may be interpreted as a sort of inverted spoonerism, where a comical phrase completely unsuitable in the context of utterance may be reinterpreted to mean something quite different. The reinterpretation depends on a substitution of the initial letter of the second element of the phrase; thus: *trouble and strife* 'wife,' *Derby Kelly* 'belly,' *apple and pears* 'stairs,' and *dickie bird* 'word.' The second element is easy enough to guess simply by running through all the rhyming words and picking the one that fits the context of utterance. As with phonestheme networks, this retrieval system depends upon sound (rhyme) and meaning in a real-world context. The rhyme is not always perfect, (e.g., *brass tacks* 'facts'), but in Cockney pronunciation, this would no doubt rhyme well, and in fact, there was a British TV program entitled *Brass Tacks*. Rhyming slang, like phonestheme networks, gives an insight into the way that the mental lexicon is stored and retrieved by means of sound and meaning.

Malapropisms

Malapropisms are slips of the tongue that occur when one word is mistaken for another similarly sounding word. They take their name from a character in Sheridan's play *The Rivals* – a Mrs. Malaprop who constantly produces such slips of the tongue, thus rendering her language *malaprop*.

Malapropisms are often amusing: *refractory table* 'refectory table' (newspaper misprint), *sitting gills* 'City and Guilds' (job application), *capable of withstanding pleasure* 'pressure' (TV newscaster), *physicist heal thyself* 'physician' (Bible reading), and '*Bach had an old spinster in the attic on which he used to practice*' 'spinet' (child's exam answer).

Cascara sugar 'caster sugar' and *garlic coffee* 'Gaelic coffee' are obvious malapropisms, whereas *bashed* or *smashed potato* for 'mashed potato' look more like variants as they both use the final *-ash* phonestheme 'contact (often violent) with a giving surface or substance.' Talking of *midges* instead of 'midgets' and speaking of the *tang* of the guitar for 'twang' are not true malapropisms as these words belong to the *mi-* 'small' and *-ng* 'lasting sound, taste etc.' phonestheme groups. The retrieval here although faulty is colored by associative phonesthetic forces connected with meaning, as well as by sound.

True malapropisms work on retrieving words from the mental lexicon on sound alone, whereas near-miss retrievals such as *midges* for 'midgets' indicate a retrieval based on sound and meaning. From such examples, as with rhyming slang and phonestheme networks, the inference may be made that the lexical storage system is cross-indexed for both sound and meaning.

Folk Etymology

Folk etymology, sometimes known as popular etymology, occurs when the origin of a word is lost or forgotten and another etymology that seems likely or fitting is substituted in the popular consciousness. The meanings of some words that have come to us from the Old English period are based on folk etymology. OE *scam-fæst* 'confirmed in shame' has now come to mean 'shame-faced,' taking the sound of

face and the connotation of blushes. In the same way, OE *brydguma* 'bridegroom' has as its second element the obsolete word *guma* 'man,' so the substitute word *groom* 'boy, male child' was used as being close in sound and meaning. These words show a slight change in form that has come about by a reinterpretation of their etymology. As with *fæst* and *guma–groom*, homophones or near homophones are often involved in folk etymology. Examples are: *free reign* for 'free rein,' *guidewires* for 'guy wires,' and colloquial *choky* for Hindustani *chauki* 'a police station.' The correlation of sound and meaning then, plays an important part in producing folk etymology, and this can be seen in a final example, *run amuck* for Malaysian *amok* 'a kind of nervous frenzy among the Malays.'

Intonation

Intonation is obviously sound symbolic when used in a sentence such as 'I've been waiting for $^{\text{a-a}}\searrow$ ges' or 'I haven't see her for $^{\text{yea}}\searrow$rs.' In both cases, the emphasis and slow enunciation of *ages* and *years* symbolize the sense of the slow passing of time. A similar use of lengthened intonation is used in the song title 'It's been a h-a-r-d d-a-ys night.' A person could be described as 'a-w-f-u-ll-y boring' where the slow intonation echoes the slow passing of time with a bore and reinforces the long /ɔ/ sound also found in the phonestheme group *brawl*, *sprawl*, *drawl* 'stretched out.' Conversely, one can snap out a command 'quick, quick, quick!' using the swift /ɪ/ phonestheme. Intonation may also go up or down as in the following short sentences echoing a parent's reaction to exam results.

'He's come $\nearrow^{\text{top}}$!' or 'He's come $\searrow_{\text{bottom}}$.'

Gesture

It has been noted that words with initial *vi*-usually denote 'intense ill temper' and that the force of this word group is due in part to the accompanying facial expression, where the labiodental /v/ is immediately followed by the spread vowel /i/, which exposes the teeth behind the lips in a sort of grimace. Such words as *vicious*, *villain*, *vindictive*, *vehement*, *vitriolic*, *vinegary*, *vixenish*, *vile* require a grinning animal-like expression indicative of aggression (Bolinger, 1965). A similar facial expression would accompany words with initial *sni-*: *sneer*, *sneak*, *sneap* (Shakespeare's 'sneaping winds') *snip*, *snitch*, *snide*.

A rising intonation usually indicates surprise, shock, or horror expressed by *oh!* or *aaagh!*, whereas delight is expressed by *ooh!* In both cases, the eyebrows will be raised and the mouth open to a greater or lesser extent. A falling intonation, however, expresses depression, disappointment, or perhaps respect or reverence. In these cases, the head will be lowered and the mouth closed.

The Iconicity of Language

Linguists such as Bolinger and Wescott speak of the iconicity of language, and by this they mean the dynamic drive of language to correlate sound and meaning.

Sound symbolism certainly is very pervasive in language in both its primary and secondary forms, and phonesthemes in particular are very widespread in English. Poets have always recognized and used sound symbolism, and now with modern psycholinguistic research that tests subjects' reactions to sounds, and modern linguistic research looking at the lexicon itself, more and more data are being gathered to prove scientifically what before was only subliminally felt.

In his article 'Linguistic iconism,' Roger Wescott (1971) posited several theories concerning the symbolic/iconic development of language. One he called 'the steady state theory' whereby the arbitrary (i.e., symbolic) function of language is balanced by the nonarbitrary iconic drive of language. As words change their meaning through time or their sounds through sound changes, so they lose their sound symbolism. However, new words are coined to fill the gaps, and if a word group becomes too iconic, as perhaps is the case with *sl-*, so new blends and coinages are short-lived. This would seem to echo the outcome of Plato's famous dialogue *Cratylus* where neither Hermogenes (supporter of the arbitrary nature of language) or Cratylus (supporter of the nonarbitrary position) seems to win. Without more detailed research, both synchronic and diachronic, it is impossible to say whether such a 'steady state' exists in language. However, it is possible to say that sound symbolism acts as a creative force within English and all other languages in the world.

Official Languages

Apartheid was a defining feature of South African society, politics, and linguistic practice for much of the 20th century. The post-apartheid democracy instituted in 1994 ushered in many changes whose consequences are already evident in the early 21st century. These changes are likely to change the social and linguistic hierarchies in the long term. The country's new constitution of 1996 surprised most observers by its recognition of 11 official languages. **Table 1** lists these languages according to numbers of speakers, according to the last census of 2001.

Of the official languages, 9 belong to the Bantu subfamily of the Niger Kordofanian languages, and 2 to the Germanic family. The Bantu languages of South Africa fall into two main linguistic subgroups, designated Nguni and Sotho, plus two other languages, Tsonga and Venda. The Nguni languages (Zulu, Xhosa, Swati, Ndebele) are largely mutually intelligible, as are the Sotho languages (Pedi (Northern Sotho), South Sotho, Tswana). Tsonga and Venda are not mutually intelligible, either with each other or with the other languages. Many of these languages have official status in neighboring territories, where they are majority languages: Swati in Swaziland, Sotho in Lesotho, and Tswana in Botswana. Ndebele, Tsonga, and Venda are also found in large numbers in neighboring countries: Ndebele in Zimbabwe, Tsonga in Mozambique, and Venda (to a smaller extent) in Zimbabwe and Zambia. The two Germanic languages, Afrikaans and English, are not mutually intelligible, but do share a great deal of cognate lexis. Afrikaans is not always described as a Germanic language, as several linguists have considered it to be a semi-creole. However, reports of mutual intelligibility with Dutch and the ability of ordinary South Africans of diverse backgrounds to service Dutch call centers based in Cape Town suggest that the case for creolization may have been overstated. **Table 2** is a regrouping of these languages according to the 'clusters' they belong to. The table also indicates alternate forms by which these languages may be designated.

Of the 11 official languages, two were official state languages in the apartheid era – Afrikaans and English. The other nine had official status in one

Table 1 The official languages of South Africa in 2001 by numbers of mother-tongue speakers

Language	*n*	*%*
Zulu	10 677 306	23.8
Xhosa	7 907 154	17.6
Afrikaans	5 983 426	13.3
Pedi	4 208 982	9.3
Tswana	3 677 016	8.2
English	3 673 197	8.1
South Sotho	3 555 189	7.9

South Africa: Language Situation

Official Languages

Apartheid was a defining feature of South African society, politics, and linguistic practice for much of the 20th century. The post-apartheid democracy instituted in 1994 ushered in many changes whose consequences are already evident in the early 21st century. These changes are likely to change the social and linguistic hierarchies in the long term. The country's new constitution of 1996 surprised most observers by its recognition of 11 official languages. Table 1 lists these languages according to numbers of speakers, according to the last census of 2001.

Of the official languages, 9 belong to the Bantu subfamily of the Niger Kordofanian languages, and 2 to the Germanic family. The Bantu languages of South Africa fall into two main linguistic subgroups, designated Nguni and Sotho, plus two other languages, Tsonga and Venda. The Nguni languages (Zulu, Xhosa, Swati, Ndebele) are largely mutually intelligible, as are the Sotho languages (Pedi (Northern Sotho), South Sotho, Tswana). Tsonga and Venda are not mutually intelligible, either with each other or with the other languages. Many of these languages have official status in neighboring territories, where they are majority languages: Swati in Swaziland, Sotho in Lesotho, and Tswana in Botswana. Ndebele, Tsonga, and Venda are also found in large numbers in neighboring countries: Ndebele in Zimbabwe, Tsonga in Mozambique, and Venda (to a smaller extent) in Zimbabwe and Zambia. The two Germanic languages, Afrikaans and English, are not mutually intelligible, but do share a great deal of cognate lexis. Afrikaans is not always described as a Germanic language, as several linguists have considered it to be a semi-creole. However, reports of mutual intelligibility with Dutch and the ability of ordinary South Africans of diverse backgrounds to service Dutch call centers based in Cape Town suggest that the case for creolization may have been overstated. Table 2 is a regrouping of these languages according to the 'clusters' they belong to. The table also indicates alternate forms by which these languages may be designated.

Of the 11 official languages, two were official state languages in the apartheid era – Afrikaans and English. The other nine had official status in one

Table 1 The official languages of South Africa in 2001 by numbers of mother-tongue speakers

Language	*n*	*%*
Zulu	10 677 306	23.8

Table 3 The four most common languages in each province

Province	*Most common language*	*Second most common*	*Third most common*	*Fourth most common*
Eastern Cape	Xhosa (5.4)	Afrikaans (0.6)	English (0.2)	S.Sotho (0.2)
Free State	S. Sotho (1.7)	Afrikaans (0.3)	Xhosa (0.2)	Tswana (0.2)
Gauteng	Zulu (2.0)	Afrikaans (1.3)	S. Sotho (1.2)	English (1.1)
KwaZulu-Natal	Zulu (7.6)	English (1.3)	Xhosa (0.2)	Afrikaans (0.1)
Limpopo	Pedi (2.8)	Tsonga (1.2)	Venda (0.8)	Afrikaans (0.1)
Mpumalanga	Swati (1.0)	Zulu (0.8)	Ndebele (0.4)	Pedi (0.3)
Northern Cape	Afrikaans (0.6)	Tswana (0.2)	Xhosa (0.1)	English (0.02)
North West	Tswana (2.4)	Afrikaans (0.3)	Xhosa (0.2)	Sotho (0.2)
Western Cape	Afrikaans (2.5)	Xhosa (1.1)	English (0.9)	Sotho (0.03)

(or more in the case of Xhosa) of the apartheid homelands.

Distribution of the Official Languages

Table 3, extrapolated from the 2001 census, shows the four most common languages per province and their numbers in millions (rounded off to the nearest 100 000).

In terms of L1 speakers per province, Table 3 shows that Zulu is in the lead (in KwaZulu-Natal), followed by Xhosa (in the Eastern Cape), Pedi (in Limpopo), and Afrikaans (in the Western Cape). The information in Table 3 can be used to show the approximate distribution of the official languages of South Africa. Table 4 shows the number of provinces in which each language is the most common, second most common, and so on. Using a weighting system of 4 points for the most common language, 3 for the second, 2 for the third, and 1 for the fourth most common languages, a ranking of the distribution of languages is possible.

Table 4 shows that Afrikaans is the language most widely distributed as a home language, followed by Xhosa. Zulu, which has the most mother-tongue speakers in the country, comes third according to provincial distribution as home language, and English is fourth. (In this article, the terms 'L1,' 'home language,' and 'mother tongue' are used synonymously.)

Unfortunately, the census statistics do not give information on the use of second languages. It is likely that English, Afrikaans, and Zulu would rank highly here. English is the most visible and audible language at governmental functions, political rallies, administration, and the upper echelons of business and education. There are also reports of incipient language shift to English among some Black South African families (see de Klerk, 2000). These factors make English a much more important language than these tables indicate. On the other hand, Afrikaans and

Table 4 The distribution of home languages per province

Language	*Most common language per province*	*Second most common*	*Third most common*	*Fourth most common*
Afrikaans	2	4	–	2
Xhosa	1	1	4	–
Zulu	2	1	–	–
South Sotho	1	–	1	3
English	–	1	2	2
Tswana	1	1	–	1
Pedi	1	–	–	1
Swati	1	–	–	–
Tsonga	–	1	–	–
Ndebele	–	–	–	1
Venda	–	–	–	1

African languages are very much alive on individual radio stations, in music, some newspapers (chiefly Afrikaans, Zulu, and Xhosa), primary education, and, to a lesser extent, on television.

Other Languages

The authochthonous (or 'most indigenous') languages of Southern Africa are in fact the Khoe-San (Khoisan) languages. These do not have official status, since their speakers have undergone language shift to Afrikaans or a Bantu language. They do have a degree of recognition as heritage languages, used for symbolic purposes. For example, the South African coat of arms carries its motto in a Khoe-San variety. Tony Traill (2002) describes the Khoe-San languages as a phylum of three unrelated groups (Northern, Central, and Southern) whose unity is more presumed than demonstrable, given the paucity of historical linguistic materials. Khoe-San languages survive to a slightly better degree in Namibia and Botswana.

South African Sign Language is an offshoot of British Sign Language, having been introduced to Cape Town by the nuns of the Irish Dominican Order in the 1860s (Aarons and Akach, 2002: 131). It is specifically mentioned in the constitution as a language to be supported by PANSALB, a government body for language promotion, because of its cultural and educational importance. For this reason and because of its use on national television in translating the news, it is sometimes informally described as the 'twelfth official language.'

Indian languages have been prominent in South Africa since 1860, with Tamil speakers reaching a maximum of about 153 645 in 1970, followed by Bhojpuri-Hindi (Bhojpuri), Gujarati, Urdu, and Telugu. These languages are now in decline, with speakers mostly having shifted to English, though many elderly bilingual speakers can be found. Malay was once prominent as one of the languages of the slave community brought from mainly the East Indies to the Cape, but it has been largely replaced by Afrikaans. Of the languages of the relatively small Chinese communities, Cantonese (Yue Chinese), Hakka (Hakka Chinese), and Mandarin (Mandarin Chinese) are prominent.

Among European languages other than the official ones, German and Portuguese are the most prominent, with smaller numbers for Dutch, Italian, Greek, and so forth. Post-apartheid openness has seen French (initially introduced in the 17th century by Huguenot refugees, only to undergo shift to Afrikaans) reintroduced, this time via francophone emigrants from different parts of Africa. Greater tolerance of African migration (beyond laboring in the mines) has seen Swahili emerge as a language to be occasionally heard on South African streets and in homes, as well as African varieties of French, English, and Portuguese.

Of classical languages, Latin, Greek, Sanskrit, Hebrew, and Arabic are prominent in mainly religious spheres.

Lingua Francas and Multilingualism

There is a high degree of multilingualism among South Africans, with many Black people – especially from the Gauteng area – claiming a command of as many as eight or nine languages (see Mesthrie, 2002: 12–13). Most people with a high school education use English as a lingua franca in formal domains and when conversing with someone they do not share a home language with. Afrikaans was a rival lingua franca for this purpose, and remains so to a decreasing extent. Other languages like Zulu or Afrikaans also function as a lingua franca, especially in informal and non-public contexts. A pidgin language, Fanakalo (Fanagalo) was prototypically used in some parts of the country in asymmetrical communication between employer and employee or in transactions in shops, petrol stations, and the like. It was a useful lingua franca of the mines, which drew on speakers of a few score languages of South Africa and several neighboring countries. Fanakalo uses a simplified Zulu lexis, with a grammar that appears to show greater influence from English than any other language. With the end of the era that spawned asymmetrical communication between Black and White, Fanakalo is slightly on the decline. The association of this pidgin with exploitation and inequality have precluded it from remaining the 'official' lingua franca of the post-apartheid mining industry. What will replace it remains to be seen.

At a more egalitarian level, when Black South Africans from different language groupings converse with each other at an informal level, one of the following may be used: (a) Zulu as lingua franca (if it is known by interlocutors), (b) code-switching between languages known by interlocutors and (c) 'township' lingua francas typically associated with young males – Tsotsi Taal (Tsotsitaal) (or Flaitaal) and Isicamtho (Camtho).

Current Initiatives

The extent to which the generous constitutional proposals regarding language are able to be implemented is still a subject of debate. Skeptics wondered about the so-called 'escape clause' in the constitution specifying that official languages are to be used in government, taking into account practicality, expense, and other circumstances (clause 3). There is also an openness of interpretation possible in clause (4), "all official languages must enjoy parity of esteem and must be treated equitably," in which 'equitable' seems to be distinguishable from 'equal.'

As a vision towards national unity and language maintenance, there is little room for discontent with the constitutional provisions. The key question for applied linguists and educators is the extent to which the new constitutional flexibility on language can be put into effective practice. In some respects, language policy and practice have been in flux in the post-1994 era, with many sectors still experimenting with the most effective and the least divisive language options. Current steps towards a national plan are now underway, with a languages bill being put before parliament. This bill ('The national language policy framework,' final draft November, 2002), which was devised by the Department of Arts, Culture, Science and Technology, would bind all government structures to a multilingual mode of operation. A 'Language in education policy' document was issued by the Ministry of Education (July, 1997) as part of the National Educational Policy Act (27 of 1996). It places emphasis on at least two languages for performance assessment and promotion. Questions about the relative roles of the mother tongue as opposed to English (and to some extent Afrikaans) as medium of instruction in schools have still to be settled. In 2004, the Minister of Education called for the use of mother-tongue instruction for three years before a switch to English as the medium of instruction (assuming this to be the language chosen by school governing bodies). The paucity of this term has concerned many applied linguists, who would favor a longer period of mother-tongue instruction. Finally, in terms of the 'Language policy for higher education' (November, 2002), tertiary institutions had to submit plans to the Ministry of Education in 2004 showing their commitment to multilingualism in their institutions.

South African Lexicography

D J Prinsloo, University of Pretoria, Pretoria, South Africa
L Pienaar, Rhodes University, Grahamstown, South Africa

© 2006 Elsevier Ltd. All rights reserved.

The first monolingual dictionary of South African English was *Africanderisms* (1913), compiled by a Methodist minister and amateur linguist, Reverend Charles Pettman. It contained definitions of the uniquely South African words he encountered, such as *veld*, *induna*, *mealie*, and *impala*. These entries were supported by illustrative quotations, in a style similar to that used by the *Oxford English Dictionary*.

Fifty-five years later, Rhodes University's Professor William Branford made the next serious attempt to document and define South African English. In 1968, he pioneered a small project to collect samples of South African English. This material, archived on thousands of handwritten or typed cards, has provided a wealth of data for various South African English dictionaries of note: Jean Branford's popular *Dictionary of South African English* (1978), the scholarly *Dictionary of South African English on Historical Principles* (1996), and, more recently, the *South African Concise Oxford Dictionary* (2002), which is an indigenized version of the 10th edition of the *Concise Oxford Dictionary*.

With 5000 entries, supported by 47 000 quotations, the *Dictionary of South African English on Historical Principles* is the result of the most extensive and detailed research ever undertaken into the history of English in South Africa. Coverage extends from the 16th century to the present day and entries include spoken as well as written forms of the language. The dictionary includes words derived from various languages which have influenced English in South Africa: Dutch, Afrikaans, and the Malayo-Indonesian, Indian, Khoisan, Nguni, and Sotho languages. Everyday words such as *robot*, *indaba*, *braai*, and *naartjie* are defined together with the language of the townships (*mellow yellow*, *spaza*, *stokvel*), local music terms (*kwela*, *mbaqanga*, *sakkie-sakkie*), mining vocabulary (*cocopan*, *cheesa-stick*, *mine-dump*), and apartheid terminology (*group areas*, *homeland*, *immorality*).

> The dictionary attempts to map and illustrate the complex landscape of that variety of English which is particular to South Africans – words borrowed from the many languages of South Africa, English words which have acquired particular senses here, and words coined for local phenomena (Silva, 1996: vii).

Recent research has highlighted the fact that South African English is not one monolithic variety, but is made up of several subvarieties, which developed along ethnic lines as a result of the apartheid policy of racial segregation. Thus, researchers have identified Black South African English (Gough, 1996), South African Indian English (Mesthrie, 1992), Cape Flats English (Malan, 1996) and Afrikaans English (Watermeyer, 1996). A notable publication in this regard is the *Lexicon of South African Indian English* (1992), compiled by the well-known sociolinguist Professor R. Mesthrie.

Other research has explored Black South African English and various subdivisions of it, e.g., Xhosa English (De Klerk, 2002) and Tswana English (Van Rooy, 2002). The different varieties of South African English do share certain core features and it is these common lexical and syntactic features that the purist might wish to term 'South African English.' However, South African lexicographers are faithful to the tradition of descriptive rather than prescriptive lexicography, and correctness is defining what is 'generally and widely used by the speakers of the language.' So it may well be that in future South African English dictionaries will have to be more inclusive, in order to capture the complex and dynamic nature of this variety of English.

Since 1994 and the scrapping of apartheid, contact between language and ethnic groups is less fraught and new lexical items are being added to South African English at an exciting rate. One of the latest of these is the very descriptive 'vuvuzela,' a term for the loud horn heard at soccer matches.

In a multilingual country such as South Africa, English is the mother tongue of a small minority, but it is used in the public domain by the vast majority, for whom it is just one of many languages in their repertoire. It is axiomatic, therefore, that English in South Africa is in a state of flux and the lexicographer has to monitor the country's linguistic scenario with an open mind and a keen eye to capture the nuances of this evolving picture.

Indic Writing

Introduction

One of the major families of scripts used in the world today derives from the system of writing first substantially recorded in Indian inscriptions of the 3rd century B.C. Historically, a great many different scripts belonging to this Indic family are attested (cf. Grierson, 1903–1927), and even today it remains exceptionally fully represented (Daniels and Bright, 1996: 371–484). Although the introduction of Islam into South Asia has resulted in the widespread diffusion there of the Arabic script to write Urdu and other languages of Pakistan, alongside these newcomers in India itself and the immediately surrounding countries of South Asia, no less than ten different scripts of indigenous origin remain in official use (see **Figure 1**) to write 13 different modern languages belonging to the Indo-Aryan and Dravidian language families, including the national languages of India, Bangladesh, Nepal, and Sri Lanka.

Figure 1 Four different scripts used to write the value '1/4 annas' in English, Hindi, Telugu, and Urdu on a postage stamp of the former state of Hyderabad.

From a quite early period, the Indic writing system also became diffused across most of Southeast Asia, in conjunction with the spread of Indian religions and cultures to that region. Numerous local adaptations of the system were developed there to write the local languages of this very diverse area, which include representatives of the Austronesian, Austroasiatic, Tai, and Tibeto-Burman language families. While some of these are now obsolete, partly as a result of the later diffusion into the region first of the Arabic script with the coming of Islam, then of the Roman script as a consequence of European colonization, the modern Southeast Asian scripts of Indic origin continue to include those used to write the national languages of Cambodia, Thailand, Laos, and Burma (Myanmar).

This article is intended to provide an overview of the historically salient common features of the Indic family of scripts, while also drawing particular attention to the distinctive typological features within the family exhibited by the modern standard scripts of South and Southeast Asia. The early spread northward of the Indic writing system into Central Asia and its continued presence there in the form of the modern Tibetan script are dealt with separately elsewhere (*see* **Tibet: Scripts**).

Early Writing in India

The primary association of the Indic writing system is with the Indo-Aryan languages mostly spoken in the northern plains of the Indian subcontinent, where they constitute a rather well defined subfamily of the Indo-European group (Masica, 1991; Cardona and Jain, 2003). While Indo-Aryan is attested over a long historical time span, distinctive cultural factors are associated with the linked issues of its historical

The early spread northward of the Indic writing system into Central Asia and its continued presence there in the form of the modern Tibetan script are dealt with separately elsewhere (*see* **Tibet: Scripts**).

Early Writing in India

The primary association of the Indic writing system is with the Indo-Aryan languages mostly spoken in the northern plains of the Indian subcontinent, where they constitute a rather well defined subfamily of the Indo-European group (Masica, 1991; Cardona and Jain, 2003). While Indo-Aryan is attested over a long historical time span, distinctive cultural factors are associated with the linked issues of its historical

evolution through different linguistic stages and the recording of these in writing. These are somewhat different from those familiar from the Middle East and Europe, where there have been long and intimate connections between writing and religious and cultural prestige.

In Indian civilization, by contrast, a marked preference throughout premodern times was given to the oral transmission of both sacred and literary texts. The Vedic hymns from around the start of the first millennium B.C., which are the oldest record of Indo-Aryan, were always preserved orally. The same was true of the vast early literature in Sanskrit, which derived from them, including the very sophisticated work of the early Brahmin phoneticians and grammarians, of whom the most famous is Pāṇini (4th century B.C.). Dissident religious movements such as Jainism and Buddhism signaled their opposition to the authority of the Vedas and the Brahmins through rejecting the Old Indo-Aryan medium of Sanskrit in favor of the later Middle Indo-Aryan languages called Prakrits, which include Pali, the sacred language of southern Buddhism. But in the earlier stages of these religions, too, scripture was typically transmitted through memory.

Writing was thus long typically associated in India only with the practical functions of administration or business. This appears to have been the case with the earliest Indian writing of all, the still undeciphered Indus Valley script, and is certainly true of the entire period before the early first millennium A.D., when the evidence for the evolution of writing derives very largely from the epigraphic evidence of royal inscriptions preserved on rock or other materials impervious to the destructive effects of the Indian climate (Salomon, 1998). The first substantial body of such evidence is found in the rock inscriptions set up by the great Buddhist ruler Ashoka (d. 223 B.C.), whose empire covered most of the subcontinent.

The Ashokan inscriptions, whose decipherment in the early 19th century was the key to the understanding of the development of Indian writing, are composed in different local Prakrits. Those located in the northwest are in the Prakrit called Gandhari, and are written in the Kharoshthi script (Figure 2). Although original in its organization, in its graphic appearance, with cursive characters running from right to left, this script clearly shows the influence of Aramaic, the chancery language of the Persian Achaemenid empire, which had earlier long controlled this region, and it has been suggested that the name 'Kharoshthi' (Sanskrit *kharōṣṭhī*, literally 'ass's ear'), may itself be of Iranian origin, with the sense of 'script of the realm' (Salomon, 2003: 93). Confined in its subsequent usage over the next few centuries to northwest India and adjacent regions of inner Asia, Kharoshthi (Das Gupta, 1958) marks only an interesting dead end from the viewpoint of subsequent Indian writing systems and therefore does not call for separate treatment here.

The Brahmi Script

All modern Indic scripts derive from the monumental Brahmi script used in the majority of the Ashokan inscriptions (Dani, 1968). Normally written from left to right, this is similar in internal organization but very different in appearance from Kharoshthi. It has been suggested that Brahmi too may have been inspired by Aramaic writing, but the evidence for this is less certain (Salomon, 2003: 87–89), and Indian scholars have naturally preferred to emphasize the originality of its creation. The name 'Brahmi' (Sanskrit *brāhmī*) indicates its early association with the creator god Brahma.

Whatever the arguments that may be advanced over the origin of individual letter shapes, the Brahmi script (like its relative Kharoshthi) certainly marks a quite new development, which is systemically different from the consonantal syllabaries used to write the Semitic languages of the Middle East. The unsuitability of these systems for Indo-European languages with their fundamental contrasts of vowels as well as of consonants was solved in the west by the invention of the Greek alphabet with its redesignation of certain Semitic letters to denote the vowels as independent graphic units fully equivalent to the consonants.

In India, the Brahmi and Kharoshthi scripts evolved a different solution. Most Prakrit syllables are open, most usually of the pattern CV. Here the consonant letter (*akṣara*) is treated as the primary graphic element. As opposed to the random order of

Figure 2 Kharoshthi script.

the Semitic and Greco-Roman writing systems, these are arranged in the Brahmi syllabary to follow the sophisticated classification of Sanskrit phonemes by the ancient Indian linguists. Their key distinction between five places of articulation (velar, palatal, retroflex, dental, labial) and five types of articulation (voiceless unaspirated, voiceless aspirated, voiced unaspirated, voiced aspirated, nasal) underlines the fundamental formal structure of virtually all subsequent Indic scripts. Closed syllables and clusters of consonants are generally infrequent in Prakrit. In the two commonest sequences of the pattern CVCCV, the medial CC consists either of a doubled consonant, where the script does not mark the gemination, or has as its first element a nasal, elegantly indicated by a diacritic mark.

The great innovation of Indic writing is its systematic indication of vowels. In the common CV units, vowel distinctions are indicated by the use of signs (*mātrā*) attached to the consonant letter, with the absence of a special vowel-sign economically marking the presence of the commonest vowel *-a*. The absence of this 'inherent vowel' is therefore logically marked by a special sign. Only independent vowels in V syllables that are word-initial or that occur internally in hiatus are indicated by special independent letters, systemically similar to the consonants and placed alphabetically before them. In terms of its generic type, therefore, the Brahmi script, like all its derivatives, is to be classed neither as a pure syllabary nor as a full alphabet, but as an intermediate category for which the name 'alphasyllabary' has come to be generally preferred.

Whatever the history of its invention (Gupta and Ramachandran, 1979), the Brahmi script (Figure 3) therefore first emerged as an already very sophisticated writing system, ideally suited to recording the language for which it was designed. As with all other writing systems, this original fit has been disturbed by subsequent phonetic changes or by the need for more or less substantial modification to write languages of a fundamentally different type. What makes the history of writing in India so remarkably is that these natural future developments were preceded by a prior process of classicization. This entailed rather profound systemic implications.

Figure 3 Rock inscription of Ashoka in Brahmi script.

The early success of Buddhism in India, which is particularly associated with the reign of Ashoka, was followed by its progressive displacement by a revived Brahminical Hinduism, culminating in the Gupta empire of the 4th–5th centuries A.D. Linguistically, this process was manifested in the replacement of the Prakrits by Sanskrit as the language of administrative record. The writing system therefore had to be adapted backward, as it were, to write the older language. As explained in 'Sanskrit in Nagari' below, some of the intrinsic phonetic complexities of Sanskrit, notably its relatively abundant sequences of consonants, could only be graphically realized at some enduring systemic cost.

Central Asian Brahmi

Of the two variants of Central Asian Brahmi, Southern Brahmi was used to write Khotanese, while Northern Brahmi was used for Tumshuqese and, occasionally, Sogdian. Both types were used to write Sanskrit, and the northern variant was also used for Tokharian and Uigur (Old Turkish).

Southern Brahmi Used for Khotanese

The Khotanese documents are written in a variety of different styles. The formal, or square, ductus, was used in all periods of the language for Buddhist literary texts. It is found in numerous calligraphic, chronological, and local variants. The earliest Old Khotanese variants are characterized by rounded corners and curved lines, while the later Old Khotanese variants usually have pointed corners and straight lines, a style that is also common in Middle and Late Khotanese. The cursive ductus, too, is found in numerous variants.

There are two vowel signs not found in Sanskrit: a pair of superscript dots ⟨-ä⟩ probably denotes a mid high vowel /ə/. A pair of superscript crossed curved lines ⟨-ei⟩ denotes a diphthong that probably resulted from the combination of $a + \ddot{a}$, different from $ai < a\text{-} + i$, but the distinction between *-ei* and *-ai* was lost early on.

The 'subscript hook,' a curly or curved line beneath an *akṣara* (commonly transcribed as an apostrophe, e.g., ⸗ ⟨pyu'⟩) may have indicated rhotacization of the vowel.

The Khotanese Brahmi was only partly adapted to the phonological system, and several ligatures not found in Sanskrit manuscripts were invented to express specific non-Sanskritic sounds and sound combinations: ⟨tc⟩ = /ts/, ⟨ts⟩ = /ts^h/, ⟨js⟩ = /dz/, ⟨ys⟩ = /z/, ⟨rr⟩ = rolled *r* (?).

Double ⟨tt⟩ was used (irregularly) to distinguish intervocalic /t/ from /d/, written single ⟨t⟩.

In the oldest manuscripts, unvoiced /ʃ/ and /ʂ/ are not distinguished from voiced /ʒ/ and /ʐ/, both being written ⟨ś⟩ and ⟨ṣ⟩. Gradually, there was a tendency to use double ⟨śś⟩ and ⟨ṣṣ⟩ for and, while /ʒ/ and /ʐ/ were always written with single ⟨ś⟩ and ⟨ṣ⟩. From Middle Khotanese on, the unvoiced pair was written ⟨ś⟩ and ⟨ṣ⟩, while the voiced pair was written with the 'subscript hook,' e.g., ⟨śi'⟩ and ⟨ṣi'⟩ = /ʒi/ and /ʐi/.

Already in the earliest manuscripts, ⟨ky⟩ and ⟨gy⟩ are interchangeable with ⟨c⟩ /tʃ/ and ⟨j⟩ [dʒ]. Syllabaries, complete or select signs only, are common in Khotanese manuscripts.

Northern Brahmi Used for Tumshuqese and Sogdian

This form of northern Brahmi contains a number of *akṣara*s also found in Uigur Brahmi, which have not yet all been satisfactorily interpreted, but probably denote several of the sounds that had no expression in the Khotanese Brahmi. These include signs for *δ* and *γ*, *w*, *z*, *ź*(*ž*), (*ʒ*), *xš*, perhaps also *γ̆*/*γ*^{w}. Several of these *akṣara*s have not yet been identified, due to the small corpuses, differing practices seen in the different manuscripts, and, probably, different usages in the three languages (because of different phonological systems). For instance, in the Tumshuqese *Karmavācanā*, *azu* 'I' is spelled ⟨asu⟩, but later ⟨azu⟩. Sogdian ⟨āžuṃ⟩ *āžun* living being' was borrowed into Uigur and Tumshuqese in this spelling, but we also find Sogdian ⟨āṣuṃ⟩ and Uigur ⟨āśuṃ⟩.

Northern Brahmi Used for Tokharian and Uigur (Old Turkish)

Tokharian and Brahmi contains a set of consonant signs (not complete) that duplicates the regular ones and are usually transliterated underscored ⟨<u>ka</u>⟩. In Tokharian, these signs are commonly assumed to have inherent -*ä*, but are also used in *virāma* position; conversely, consonant signs without corresponding duplicate signs are spelled with ⟨-ä⟩ in *virāma* position. The only such character used in Tumshuqese is ⟨<u>ra</u>⟩, which appears to take the place of ⟨rä⟩.

Uigur Brahmi uses ligatures with ⟨-y-⟩ to express front (umlauted) vowels, e.g., ⟨kyo⟩ = *kö*.

North Indian Scripts

Modern Northwestern Scripts

Before turning to the description of Nagari, the most important modern Indian script, and the one that most fully exemplifies the implications of the Sanskritization of Indian writing, attention may be drawn to a less commonly noticed development in the opposite direction of simplification. This is chiefly exemplified by the commercial shorthands (Figure 4), generically labeled 'Mahajani' (Hindi *mahājanī* 'mercantile'), which are now increasingly obsolete, but which were formerly used for many centuries as business and revenue scripts in a great variety of regional forms. Best exemplified for the northwest (Leitner, 1883), these characteristically dispense with most modifying vowel signs, although vowel letters are sometimes erratically inserted as *matres lectionis*. Like most shorthands, they are accordingly easier to write quickly than to read accurately, hence the proverbial misreading of graphic ⟨bb 'jmrgy bṛbh bhj djy⟩, i.e., *bābā ajmēr gayā baṛī bahī bhēj dījiyē* 'the "master has gone to Ajmer, send the big ledger,' as *bābā āj mar gayā baṛī bahū bhēj dījiyē* 'the master died today, send the chief wife!' (Grierson, 1899: 3).

There was also formerly in existence a category of fully voweled scripts, again particularly well represented in the northwest, which might be termed 'semi-learned' in view of their intermediate typological position between these commercial shorthands on the one hand and the learned northern scripts of the Nagari type on the other. Now mostly obsolete, these semi-learned scripts once included the Kaithi script associated with the scribal Kayasth caste of northern India (Grierson, 1899), the Khojki script of the Khoja Ismaili Muslims of western India (Shackle and Moir, 1992: 34–42), and the Hindu-Sindhi script abortively promulgated by the British in the late 19th century.

Figure 4 Mahajani writing.

The most successful survivor of this group is the Gurmukhi script (Shackle, 2003: 594–598), which has sacred associations with their scriptures (Panjabi *gurmukhī* 'belonging to the Guru-guided ones') to the Sikhs, and which is today the standard script for writing Panjabi in India. Although the letter shapes of the Gurmukhi script are similar to those of Nagari, its organization is generally closer to the original model of Brahmi than to the classicized norms of Nagari with their insistence on the special writings of consonant groups as graphic clusters. The doubled consonants so generally retained from Middle Indo-Aryan in Panjabi (unlike most New Indo-Aryan languages) are thus indicated as in Brahmi by writing a single consonant versus the clusters obligatory in Nagari, so Panjabi ⟨makhan⟩ = *makkhan* 'butter' versus Hindi ⟨makkhan⟩. A modern Gurmukhi refinement, doubtless inspired by the Arabic *tashdīd* used in Urdu orthography, indicates such doubling by a superscript semicircle (*addhik*), but its use remains erratic.

The number of letters is also reduced, to 35 as compared to the 43 in Nagari, through the reduction of the basic vowel letters to three and the absence of consonant letters distinguished only for Sanskrit; and in place of the consonant clusters that swell the graphic inventory of most Indian scripts, Gurmukhi adds to its basic consonant letters only a few subscript marks, to indicate *-r* and *-h* (and a rarely used *-v*). It may also be noted that the number of Panjabi consonant phonemes is reduced from the usual Indo-Aryan set by the reduction of voiced aspiration to tone, so written Gurmukhi ⟨ghoṛā⟩ 'horse' is realized as ⟨k'òṛā⟩ with partial devoicing and low-rising tone. Since the incidence of the Panjabi tones is largely predictable, their historical Gurmukhi spelling is only partially comparable to the more elaborate adaptations of the Indic writing system to write the fully tonal languages of Southeast Asia that are considered in section 'Tonal Scripts' below.

Sanskrit in Nagari

The more typical post-Brahmi line of development is best illustrated by reference to Nagari, both the most widely spread modern north Indian script and the most prestigious as the result of its long particular association with Sanskrit. As the best documented of the Indian scripts, the evolution of Nagari (Singh, 1991) is associated with the elaboration of Brahmi norms, as writing in India was adapted from its original association with Middle Indo-Aryan to provide a close representation of the syllabically much more complex structures of classical Sanskrit (Salomon, 2003: 75–78), the sacred language of revived Hinduism. The more immediate ancestor of the north Indian scripts is the imperial Gupta script of the 4th–6th centuries A.D. From this script are derived the Khotanese and the modern Tibetan script, while its numerals are the direct ancestor of the Arabic numerals, which were in turn transmitted to Europe. By the 11th century A.D., the Gupta script had developed into the script whose standard status in northern India is indicated by the name 'Nagari' (*nāgarī* probably meaning 'city script'), and whose characteristic square-shaped syllabary reflects its typical writing by pen with Indian ink. The alternative name Devanagari (*dēvanāgarī* 'script of the city of the gods') indicates the particular association with Sanskrit which has important implications for its organization.

The inventory of signs was extended to include letters and diacritics to mark a number of archaic features peculiar to Sanskrit, such as the syllabic liquid *ṛ* or the triple distinction of sibilants. The order of the syllabary is illustrated in Figure 5. The indepen-

Figure 5 Nagari as used for Sanskrit.

dent vowels come first, followed by the five key classes of 25 consonants, then the eight other consonants and semi-vowels. The alphabetical arrangement according to vowel length and consonantal position, aspiration, and voicing, reflects the sophistication of the Sanskrit phoneticians. All consonant letters are regarded as containing the inherent vowel *-a*, with other vowels in CV syllables being variously indicated not only by following strokes (for *-ā, -ī*), but also by a preceding stroke (for *-i*), by subscripts (for *-u, -ū, -ṛ* and the three very rare following vowels), by superscripts (for *-ē, -ai*), or by following strokes with superscripts (for *-ō, -au*). Simple vowels are alphabetically preceded by nasalized vowels, indicated by a superscript dot (*anusvāra*) and by vowels followed by a voiceless *-ḥ* (*visarga*).

In contrast to Middle Indo-Aryan, Sanskrit has numerous closed CVC or CCVC syllables. In order to accommodate the resulting frequent sequences of two (less often of three) consonants, a quite elaborate inventory of some 170 conjunct clusters was developed, in which a part of the first consonant is typically joined to a full form of the second, although there are instances in which the first element is graphically dominant and others in which the elements are hardly discernible. A considerable element of complexity running counter to the natural logic of the original writing system is thus introduced, while further conventions are used to mark the very common Sanskrit combinations with *-r-*, with a short subscript stroke being used to indicate postconsonantal *-r-*, while a special convention denotes closed syllables ending in *-r* by a superscript hook (*rēpha*) written above the following consonant. The difficulty of reading Sanskrit is considerably increased by the conventions of word sandhi, in which the final letter of one word in a verse or sentence is combined by a careful set of rules with the initial letter of the next, resulting in long graphic sequences joined by a continuous horizontal line from which the letters appear to hang.

Modern Languages in Nagari

This convention was continued in the writing of Hindi and other New Indo-Aryan languages in Nagari until it was abandoned in favor of Western-style word division with the introduction of printing to India from the early 19th century onward. The indigenous vertical stroke used as an equivalent of the full stop was amplified by the borrowing of English punctuation marks, along with such graphic devices as bold or italic styles, although the distinction in the Roman script of capital and lower-case letters has remained alien to the principles of Indic writing.

Other modern innovations in the Nagari script as used for Hindi (Lambert, 1953; Shackle and Snell, 1990: 26, 35–37) include the distinction of additional consonants by use of a subscript dot. These include the marking of *ḍ ḍh* to indicate the retroflex flaps *ṛ ṛh*, and of *k kh g j ph* to mark sounds found in Persian and English loans, *viz., q kh g z f*. In writing the numerous *tatsama* loans from Sanskrit, on the other hand, Hindi follows the example of most other modern Indian languages in preserving the Sanskrit spellings even where phonemic distinctions have long been lost, as in the case of the retroflex *ṇ* and *ṣ*. Similarly, as in most other modern scripts, the battery of conjunct consonants continues to be employed to write Sanskrit loans, in spite of their considerable awkwardness for printing or typing (though they are more easily computer-generated).

Both the most ambiguous and the most cumbrous features of Hindi orthography concern the writing of consonants in non-CV contexts. The absence of the inherent vowel *-a* must be indicated in Sanskrit by a short subscript stroke (*virāma,* Hindi *halant*), a resource often employed in printed Hindi to indicate the first member of graphically awkward consonant combinations. As a consequence of post-medieval phonetic change, Hindi has lost postconsonantal *-a* in nearly all final and many medial positions, rendering the use of *halant* redundant if at the cost of ambiguity. Thus, in native words, written ⟨kara⟩ and ⟨karanā⟩ correspond to *kar* 'do!' and *karnā* 'to do.' But in loans from Perso-Arabic and English, the *tatsama* system of conjunct clusters, including the superscript *rēpha* (H *rēph*), is generally employed, so for example *farz* 'duty,' *vārḍ* 'ward,' *kartā* 'creator' are spelled ⟨farja, vārḍa, kartā⟩. A double system of orthography also prevails in the writing of noninitial clusters composed of nasal with homorganic plosive, for which two conventions are in simultaneous use, either that already established in Brahmi of using a superscript mark of nasalization, or the alternative use of a conjunct consonant, hence for *hindī* 'Hindi' alongside the preferred ⟨hiṃdī⟩, the spelling ⟨hindī⟩ is also possible (Figure 6). Another superscript mark of

Figure 6 Nagari as adapted for Hindi.

(*candrabindu*) is used to indicate vowel nasalization, which is phonemically distinctive in Hindi.

Although Marathi and Nepali share the Nagari script, their autonomy from Hindi is jealously preserved. A distinctive typeface is used in printed Marathi, which employs numerous orthographic conventions not found in Hindi, including an additional letter for retroflex *ḷa*, added to the end of the syllabary (as is also done in the Gujarati and Oriya scripts). The separate status of Nepali as a national language is symbolically demonstrated by the extensive use of the *halant* and conjunct consonants to indicate the absence of the inherent *-a*, and by deliberate preference for conjuncts rather than marks of nasalization to write nasal clusters.

Other North Indian scripts

Still more distinctive are the proudly preserved separate scripts used to write other north Indian languages. The other modern north Indian scripts (Masica, 1991: 137–351; Salomon, 2003: 80–83) share with Nagari the tendency for handwriting to be closely linked to printed forms, i.e., to be only semicursive in nature. Their autonomy is guaranteed by a visual appearance so distinctive as to prevent ready mutual comprehension (Figure 7).

John 3:16 in Hindi:

क्योंकि परमेश्वर ने संसार से ऐसा प्रेम रखा कि अपना एकलौता पुत्र दे दिया, कि जो कोई उस पर विश्वास करे, नष्ट न हो, परंतु शाश्वत जीवन पाए।

⟨kyoṃki parameśvara ne saṃsāra se aisā prema rakhā ki apanā⟩
kyoṃke parmeśvar ne sansār se aisā prem rakhā ke apnā
⟨ekalautā putra de diyā, ki jo koī usa para viśvāsa kare,⟩
eklautā putr de diyā, ke jo koī us par viśvās kare,
⟨naṣṭa na ho, paraṃtu śāśvata jīvana pāya.⟩
naṣṭ na ho, parantu śāśvat jīvan pāe.

John 3:16 in Panjabi (Gurmukhi)

ਕਿਉਂਕਿ
ਪਰਮੇਸ਼ੁਰ ਨੇ ਜਗਤ ਨੂੰ ਅਜਿਹਾ ਪਿਆਰ ਕੀਤਾ ਜੋ
ਉਹ ਨੇ ਆਪਣਾ ਇਕਲੌਤਾ ਪੁੱਤ੍ਰ ਬਖ਼ਸ਼ ਦਿੱਤਾ ਤਾਂ ਜੋ
ਹਰੇਕ ਜੋ ਉਸ ਉੱਤੇ ਨਿਹਚਾ ਕਰੇ ਹਲਾਕ ਨਾ ਹੋਵੇ
ਪਰ ਸਦੀਪਕ ਜੀਉਣ ਪਾਵੇ

John 3:16 in Gujarati

કેમ કે દેવે જગત પર એટલી પ્રીતિ કરી
કે તેણે પોતાનો એકાકીજનિત દીકરો આપ્યો,
એ સારુ કે જે કોઈ તેના પર વિશ્વાસ કરે તેનો
નાશ ન થાય, પણ તે અનંતજીવન પામે.

John 3:16 in Bengali

কারণ ঈশ্বর জগৎকে এমন প্রেম করিলেন যে, আপনার
একজাত পুত্রকে দান করিলেন, যেন, যে কেহ তাঁহাতে
বিশ্বাস করে, সে বিনষ্ট না হয়, কিন্তু অনন্ত জীবন পায়।

John 3:16 in Oriya

କାରଣ ଈଶ୍ୱର
ଜଗତକୁ ଏତେ ପ୍ରେମ କଲେ ଯେ ସେ ଆପଣା
ଅଦ୍ୱିତୀୟ ପୁତ୍ରଙ୍କୁ ଦାନ କଲେ, ଯେପରି ଯେ କେହି
ତାହାଙ୍କଠାରେ ବିଶ୍ୱାସ କରେ, ସେ ବିନଷ୍ଟ ନ
ହୋଇ ଅନନ୍ତ ଜୀବନ ପ୍ରାପ୍ତ ହୁଏ ।

Figure 7 North Indian scripts.

The modern Gujarati script is a more recent offshoot from Nagari (which is still employed for printing Old Gujarati texts), being a 19th-century standardization of the local semi-cursive hand, hence its distinctive lack of the Nagari horizontal word stroke. Rules for word division in Gujarati follow Marathi rather than Hindi norms in such matters as the writing of postpositions together with their preceding noun.

In the northeast, the separate status of the proto-Bengali script is attested from at least ca. 1000 A.D., although the standardization of the spikily elegant modern Bengali script dates, as with Nagari, from the 19th century. Although similar in systemic organization to Nagari, the Bengali script (Banerji, 1919) masks numerous unpredictable phonetic realizations that are the result of a considerable process of phonetic change. The same script is also used to write the phonetically more conservative Assamese, which is distinguished from its more prestigious neighbor by a few minor but distinctive graphic conventions. The Oriya script is a separate offshoot from proto-Bengali, in which the letter shapes are dwarfed by large circular flourishes describing 'umbrellas' above them. As in the case of the south Indian scripts, notably the neighboring Telugu (see 'Dravidian' below), which the Oriya script superficially resembles, these are thought to originate from the need imposed by the traditional local method of writing by incising with a stylus on palm leaves to avoid horizontal strokes likely to tear the leaf.

The fundamental structural features described for Nagari govern these three scripts also, besides others surviving until the 20th century, like the Sharada script formerly used to write Sanskrit by the Brahmins of Kashmir. All, for instance, share the distinctive rules of historical spelling for Sanskrit *tatsamas* as a separate orthographic subsystem, also like the different set of rules for the phonetic realization of the graphically inherent *-a,* although the various phonemic structures of Gujarati, Bengali, Assamese, and Oriya naturally determine particular local orthographic conventions. While in no modern country are so many parallel writing systems in use as in India, there is little prospect of a reduction in their number, since following from the development of print capitalism and a modern education system during the 19th century, scripts have become very powerful cultural symbols of regional linguistic identity. At a broader level, the successful resistance of the north Indian scripts to the challenges offered by the Arabic and Roman scripts is, while certainly not unaffected by religious chauvinism, undoubtedly also due to their accuracy and economy in indicating such typical features of north Indian languages as contrastive consonantal aspiration or the key phonemic distinction between retroflex and dental articulation, which other systems of writing can be only clumsily adapted to express by means of diacritics.

South Indian Scripts

The most obvious generic difference between the scripts of southern India and most of the northern scripts (other than the special case of Oriya) is that the letter shapes are typically rounded or circular rather than square in appearance (Figure 8). These differences in outward form, originating from the preferred use in the south of palm leaves as a writing material, are, however, on the whole more significant than differences in structural organization. This rule of difference in visual form but virtual identity in system is naturally particularly true of scripts used in the south (Sivaramamurti, 1966) to write Sanskrit, whose most important classical exemplar is the Grantha script, widely used from about the 6th century B.C. down to recent times.

(a) Sinhala

(b) Telugu

(c) Kannada

(d) Malayalam

(e) Tamil

Figure 8 South Indian scripts.

Sinhala

The Grantha script was a significant influence in the complex evolution of the script used to write Sinhala (Gunasekhara, 1891: 3–66), the southernmost of the Indo-Aryan languages, which has developed independently of the main northern bloc since its first establishment by emigration to Sri Lanka around the 5th century B.C. Since Sri Lanka is the one place in South Asia where Buddhism survived as the dominant religion, the Sinhala script is also used there for writing Pali.

The full Sinhala script (*misra hodiya*) accordingly possesses the full set of Sanskritic letters, used in writing Sanskrit and Pali loanwords. But Sinhala itself has lost numerous distinctions, notably that between aspirated and unaspirated consonants, while developing new contrasts of its own. The extended inventory of vowels includes both short and long *æ e o,* each distinguished by new letters and diacritics in the simplified classical Sinhala syllabary (*elu hodiya*), which also adds four letters for the special Sinhala half-nasal consonants *ng, nd, nd, mb* and the retroflex *ḷ*.

Dravidian

The Dravidian languages of peninsular south India (and northern Sri Lanka) were the first non-Indo-Aryan languages to which the Indic writing system was successfully adapted. All these scripts are ultimately derived from the same Brahmi source, through different lines of descent in which the script associated with the Pallava dynasty of the 3rd–8th centuries A.D. plays an especially important role. There is a visually distinctive script (Bright, 1998; Krishnamurti, 2003: 78–89) for each of the four major modern Dravidian languages, Telugu, Kannada, Malayalam, and Tamil (the official state languages respectively of Andhra Pradesh, Mysore, Kerala, and Tamilnadu) and any attempts to rationalize the distinctions between them have been quickly countered by the embattled partisans of local ethnolinguistic identities.

The long coexistence of the Dravidian languages with Indo-Aryan has to some extent helped overlay the fundamental differences of the two language families in grammar and native vocabulary. Thus, on the one hand, the characteristic Indo-Aryan distinction of retroflex from dental consonants is itself plausibly explained by early Dravidian influence, while on the other the prolonged influence of Sanskrit has shaped the higher registers of all the Dravidian languages in varying degrees. Dravidian phonetic structures (marked by a preponderance of CV syllables and by consonant combinations mostly consisting either of geminates or of combinations with liquids or beginning with homorganic nasals) have a high degree of intrinsic compatibility with the basic principles of writing originally developed for Middle Indo-Aryan, and this compatibility has come to be reinforced by the adoption of many further devices of the familiar Sanskritic type.

Telugu

The clearest instance of these characteristics is provided by the script used to write Telugu, situated in the northeast of the Dravidian territory and long in close contact with Indo-Aryan. The script is descended from the medieval script used to write both Telugu and Kannada, which belongs to a different branch of Dravidian. Nineteenth century standardization resulted in the two modern scripts being carefully distinguished from one another. The Telugu script (Krishnamurti and Gwynn, 1985: 3–37) is now markedly circular and curly in appearance, while the equally elegant Kannada script is somewhat more linear.

The standard Dravidian distinction between long and short *e* and *o* is marked in the Telugu script, although (unlike Sinhala) it does not possess special vowel signs to mark the modern phonemic distinction of *æ* (from *ē*). The inherent vowel *-a* is indicated by a tick (*talakaṭṭu*) placed over most consonants, with its cancellation for an unvoweled consonant being indicated by a distinct superscript. The placing of other vowel signs is typically more restricted than in Nagari, usually above or after the consonant, partly no doubt as a consequence of the special rules for writing consonant combinations, which are discussed below.

As with all adaptations of the Indic writing system to non-Indo-Aryan languages, the chief redundancy concerns the inbuilt graphic distinction of the two aspirated series *kh ch ṭh th ph* and *gh jh ḍh dh bh* from the corresponding unaspirated letters. So while the Telugu script's consonant inventory is of the Indo-Aryan type, the aspirate letters regularly written in loans are not systematically realized in pronunciation. Their subsidiary status is graphically indicated in the formation of many of them by the addition of a diacritic to the corresponding unaspirated letter.

The most notable systemic divergence of the Telugu script from the northern norms exemplified by Nagari concerns the writing of consonant combinations (**Figure 9**). Those whose first element is a homorganic nasal are written in the usual way with the nasal sign *anusvāra,* though this is here a full circle looking like an independent letter rather than a superscript dot as in the northern scripts. But whereas Nagari writes geminates and other consonant combinations by juxtaposing a truncated form of the first element with a fuller form of the second to

Nagari:

स त	sa + ta	=	स्त	sta
स व	sa + va	=	स्व	sva
त र य	ta + ra + ya	=	त्र्य	trya
पुस्तक	pustak(a)		'book'	
स्वतंत्र्य	svatantry(a)		'independence'	

Telugu:

స	sa + ta	=	స్త	sta
స వ	sa + va	=	స్వ	sva
త ర య	ta + ra + ya	=	త్ర్య	trya
పుస్తకం	pustakaṃ		'book'	
స్వతంత్ర్యం	svatantryaṃ		'independence'	

Figure 9 Nagari-Telugu contrasts.

which most vowel diacritics are typically attached, the Telugu script prefers to write the full form of the first element, to which vowel diacritics are attached, with the second element being added as a subscript after the vowel diacritic. Many of the commonest of these subscripts are graphically distinct from the base forms, and combinations with *-r* are written with a subscript placed before the first consonant.

Tamil

From another line of descent has resulted the modern script used to write Malayalam. This script, with its full set of Indo-Aryan letters, is structurally fairly similar to the Telugu script, although the Malayalam language is most closely related to Tamil, the Dravidian language that has the longest recorded history and is the one least influenced by Indo-Aryan in its core features.

In keeping with this separate identity of Tamil, which has been emphasized by an often chauvinistic Dravidian nationalism, the Tamil script is very different from all the other Dravidian scripts in many features of its organization, and represents the most radical restructuring in South Asia of the Brahmi system. Tamil writing is first attested in inscriptions of the 2nd century B.C. (Mahadevan, 1971), with the modern script recognizably emerging around the time of the Chola dynasty in the 11th century A.D. Its basic organization (Hart, 1992: ix–xx) continues to reflect the original development of the script to write classical Tamil, so that later features are not always represented.

Letters and diacritics (Figure 10) are used to distinguish the usual 10 Dravidian vowels, including short and long *e* and *o*. The 33 Indo-Aryan consonant letters are much more radically reduced in the Tamil script, to only 18. Within the five core classes, there are separate letters only for the voiceless stops *k c ṭ t p* (in modern Tamil often realized as voiced consonants), alternating in the alphabetical order with the corresponding nasals *ṅ ñ ṇ n m*. These are followed by the four liquids *y r l v*, then by the distinctive Tamil approximant *ẓ* (also transliterated *l̲*), the retroflex *ḷ*, and the letters transliterated *r̲* and *n̲*, which were originally alveolars phonemically distinct from both the retroflex and the dental series. Five extra letters are added to this set from the Grantha alphabet to write the sounds *j ṡ s h kṣ* in Sanskritic and other loanwords.

The recasting of the Tamil script as an alpha-syllabary of appreciably distinctive type within the Indic family is further exemplified in the extensive use of the superscript dot (*puḷḷi*) for the systematic denotation of unvoweled consonants, including the first member of consonant combinations, other than the homorganic nasal indicated by a circle as in Telugu. The complexities involved in the writing of all other South Asian scripts through the use of conjunct consonants are thus neatly eliminated. The further standardization in 1978 of the forms of vowel signs (also carried out in Malayalam) has helped bring the Tamil syllabary rather closer than other South Asian scripts to the alphabetic model, though it remains distinguished from that model by the continuing graphic subordination of the vowel signs to the consonant letter that heads the syllable.

Southeast Asian Scripts

Writing in Southeast Asia

Indic scripts were introduced to the islands and mainland of Southeast Asia in the early centuries of the first millennium A.D. as a part of the complex process of the transmission of Indian civilization, which constitutes such a historically remarkable instance of peaceful cultural diffusion. The paleographic record (De Casparis, 1975) shows a variety of early Indic scripts to have been in local use, at first mostly for the writing of Sanskrit, with a characteristic predominance of the southern Pallava type.

Both the great linguistic diversity of Southeast Asia and the complexity of its early history, in which numerous kingdoms and empires permeated first by Hindu then in the countries of the mainland by Buddhist religious and cultural values vied with one

another for local supremacy, mean that it is not always possible to discern in detail how the Indic writing system was variously adapted to write Southeast Asian languages, beginning with the Old Mon inscriptions dating from the later part of the first millennium A.D.

Here only the principal systemic differences dictated by the variety of indigenous language types are outlined. As a necessary preliminary, it should be observed that Southeast Asian languages possess neither the characteristic Indic distinction between retroflex and dental, nor the full set of Indo-Aryan contrasts of voicing and aspiration.

As a result, while these features of the system may be graphically preserved as necessary to write Sanskrit and Pali loanwords, they are essentially redundant to the writing of Southeast Asian languages. At the same time, the numerous Indic loanwords from Sanskrit and Pali constitute an important subsystem in all Southeast Asian writing systems, with special pronunciation rules often very different from those mechanically suggested by their preserved Indian spellings

Non-tonal Scripts

The linguistic divergence from Indo-Aryan norms is least marked in the case of the Austronesian languages of insular Southeast Asia, with their typical absence of tonal features and general preference for simple syllabic structures of the CV type. For writing these languages, there were formerly in use a large number of local scripts (Kuipers and McDermott, 1996), but all have been made obsolete or obsolescent by the general spread of the Roman script to write Indonesian, Tagalog, and the associated local languages of Indonesia and the Philippines. Historically, the most significant is the Kawi script used until the early 20th century to write Javanese (Dumont, 1923) until its modern replacement by Roman. This is a straightforward syllabary similar to South Indian scripts in its use of subscripts to write consonant clusters, but of a distinctive sloping style (Figure 11), with a restricted set of consonant letters, which instead of the Indic alphabetic order follows the saying *hana caraka, data sawala, padha jayanya, maga bathanga* 'There were two emissaries, they began to fight, their valor was equal, they both fell dead.'

Cambodian, which belongs to the Mon-Khmer branch of the quite different Austroasiatic family, is also a non-tonal language. But the Cambodian script is considerably more complex than those devised for the insular languages of Southeast Asia. Not only is the proportion of vowel to consonant phonemes in Cambodian intrinsically very different from the Indo-Aryan system for which Indic writing was devised, but further complexities have been introduced by the considerable phonetic changes that have taken place over the centuries since the script was first devised.

In contrast to the modern scripts of South Asia, Cambodian and the other three standard modern Southeast Asian scripts of Indic origin (Figure 12)

Figure 11 Javanese in Kawi script.

do not mark word division by spacing. The Cambodian script (Huffman, 1970) follows the familiar principles of the alphasyllabary, with the second members of the consonant clusters that are frequent at the beginning of syllables indicated by special subscripts and with vowel signs written in various positions around the main consonant. Except in Indic loans, however, the letter added to the alphabetic series to write the glottal stop is used to introduce all initial vowels. The formal internal organization of the Cambodian syllabary is otherwise also of the Indic type, but the restricted number of consonant phonemes means that the aspirated and retroflex series are largely redundant, while a much expanded inventory of 21 vowel signs is needed to represent the rich inventory of vowel phonemes. A further systemic complexity results from the modern pronunciation of the original voiced consonants ⟨g j d b⟩ as unvoiced /k c t p/ but with breathy phonation of the following vowel, which may itself be pronounced quite differently from the vowel written with the same sign after an original voiceless consonants, so, for example, written ⟨kā⟩ corresponds with phonetic /ka:/ but written ⟨gā⟩ is realized as phonetic /kiə/ with special phonation.

Tonal Scripts

Many of the distinctive features outlined for Cambodian are also true of the other Southeast Asian scripts, including the use of the glottal stop as the bearer of initial vowels, the addition of extra vowel signs to accommodate a larger vowel inventory, the redundancy of many consonants except to preserve the historical spellings of Indic loanwords, and the further complexities introduced by phonetic changes since the individual scripts were first evolved in the early medieval period as adaptations of the Old Mon writing system.

But Thai and Lao, both members of the Tai language family, as well as Burmese, belonging to the Tibeto-Burman family, are also languages with a high proportion of monosyllabic words distinguished from one another only by phonemically distinctive tones, for which Indic writing provided no intrinsic method of indication. In the case of the Thai script (Danvivathana, 1987), the innovative use of superscript signs to indicate tones – apparently the first use of tonal marks in any of the world's writing systems—is traditionally attributed to King Ramkhamhaeng (d. 1298). The modern form of the script is, however, due to the reforms of later kings down to the 20th century, Thailand being the only country in the entire Indic script region (other than Tibet) never to have been subjected to European colonial rule. As in Cambodian, secondary phonetic developments in the language since the original devising of the script have resulted in a complex system in which the five modern tones are indicated not only by the four tone signs but also by initial consonants, so that while, for example, written ⟨k⟩ represents phonetic /k/, written ⟨k g gh⟩ all represent phonetic /kh/ but with different tonal implications. This preservation of historical spellings results in 44 consonant graphemes representing only 21 consonant phonemes, as opposed to a much closer match between 19 vowel signs and 21 vowel phonemes.

Lao is closely related to Thai and employs a similar-looking script (Diller, 1996), which like the Cambodian script successfully saw off brief attempts by the former French colonial administration to give official currency to the Roman script, as had been done in Vietnam. The preponderance of consonant letters intrinsic to most Indic writing systems has, however, been reduced in the modern Lao script by the elimination of historical doublets, resulting in only 27 consonant graphemes for the 20 Lao consonant phonemes.

The Burmese script (Roop, 1972) was also originally developed from the Old Mon script, but along

South Asia as a Linguistic Area

K Ebert, University of Zurich, Zurich, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The roughly 450 languages of South Asia belong to four different language families: Indo-European, Dravidian, Austroasiatic, and Sino-Tibetan. There are three small isolates, Burushaski, Nahali, and Kusunda (probably extinct). Speakers of Indo-Aryan (IA) languages constitute 78% of the inhabitants of South Asia, followed by Dravidian (DRAV) speakers with 20%; speakers of Austroasiatic, i.e., Khasi and Munda (MU), and Tibeto-Burman (TB) languages together do not constitute more than 2%. The number of speakers is reflected in the space devoted to languages in the sprachbund literature. Emeneau, the first authority on the subject, wrote about 'India as a linguistic area' (1956). Although Nepal and Bhutan also belong to South Asia, languages of the Himalayas are seldom included in the sprachbund literature, nor are languages of Nagaland or Meghalaya.

I shall first look at the features most often mentioned as characterizing the area. After a brief summary of the history of the field, I shall discuss the possibility of interpreting the linguistic data as evidence for earlier settlement patterns and migrations. The last section stresses the need for more detailed investigation of subareas.

Areal Features

The following features are mentioned in most of the literature on the South Asian sprachbund:

South Asia as a Linguistic Area

K Ebert, University of Zurich, Zurich, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The roughly 450 languages of South Asia belong to four different language families: Indo-European, Dravidian, Austroasiatic, and Sino-Tibetan. There are three small isolates, Burushaski, Nahali, and Kusunda (probably extinct). Speakers of Indo-Aryan (IA) languages constitute 78% of the inhabitants of South Asia, followed by Dravidian (DRAV) speakers with 20%; speakers of Austroasiatic, i.e., Khasi and Munda (MU), and Tibeto-Burman (TB) languages together do not constitute more than 2%. The number of speakers is reflected in the space devoted to languages in the sprachbund literature. Emeneau, the first authority on the subject, wrote about 'India as a linguistic area' (1956). Although Nepal and Bhutan also belong to South Asia, languages of the Himalayas are seldom included in the sprachbund literature, nor are languages of Nagaland or Meghalaya.

I shall first look at the features most often mentioned as characterizing the area. After a brief summary of the history of the field, I shall discuss the possibility of interpreting the linguistic data as evidence for earlier settlement patterns and migrations. The last section stresses the need for more detailed investigation of subareas.

Areal Features

The following features are mentioned in most of the literature on the South Asian sprachbund:

- retroflex consonants
- OV word order
- converbs ('conjunctive participles')
- compound verbs
- the quotative
- morphological causatives
- dative subjects.

Retroflex Consonants

All the major languages of South Asia have a phonemic opposition between retroflex and dental consonants (Ramanujan and Masica, 1969). Many IA and most DRAV languages also have retroflex ṛ, ṇ, and ḷ. There are no retroflexes in Assamese and in South MU nor in Indo-European. Kuiper's (1967) demonstration of the increasing frequency of retroflex consonants in the successive books of the *Rigveda* is generally accepted as proof of DRAV substratum influence.

OV Word Order

The second feature, OV word order, holds for languages from Pakistan to Assam and from Nepal to Sri Lanka. The only two exceptions are Kashmiri (IA) and Khasi (AA), which are both VO. However, OV word order also characterizes the languages of Central and Northeast Asia, including Korean and Japanese.

Converbs

This feature has been extensively discussed in the sprachbund literature. But although most languages of the subcontinent have at least one converb (conjunctive participle, gerund), there are considerable differences in detail. The most general or sequential converb can fulfill a number of functions, depending on the existence of more specific converbs. Hindi has only one form (*-kar/-ke*), which has a broad range of applications. The following examples illustrate sequential, modifying, and causal interpretations of the Hindi and Tamil general converbs.

(1) HINDI (IA)

a. us-ne nahaa-**kar** khaanaa khaa-yaa
he-ERG *bathe*-CONV *meal* *eat*-PFV:3SG:MASC
'Having bathed he ate his meal'

b. vah dhauṛ-**kar** aa-yaa
he *run*-CONV *come*-PFV:3:SG:MASC
'He came running'

c. vah raat din kaam kar-**ke** biimar par ga-yaa
he *night* *day* *work* *do*-CONV *ill* *fall* GO-PFV:3SG:MASC
'He fell ill because he worked day and night'

(2) TAMIL (DRAV)

a. avan iŋkee va-**ntu** enn-ai.k kuuppiṭṭ-aan
he *here* *come*-CONV I-ACC *call*:PT-3SG:MASC
'He came here and called me'

b. avan ooṭ-**i** va-nt-aan
he *run*-CONV *come*-PT-3SG:MASC
'He came running'

c. maẓai pey**tu** kuḷam niṛai-yum
rain *fall*:CONV *pond* *fill*-FUT:3SG:NEUT
'It rained and (therefore) the pond will fill'

Most languages have a simultaneous or modifying converb different from the conjunctive participle, which is often reduplicated. See the following examples with Hindi (1b), and Tamil (2b).

(3) ORIYA (IA) baṭɔre ja-**u** ja-**u**
'walking along the road'
MALTO (DR) eek-**no** eek-**no** paawno
'walking along the road'
ATHPARE (TB) huk-**sa** huk-**sa** abe
'he came down barking'

(The sequential converbs are Nepali *-ii, -era*, Oriya *-i, -iki,* Malto */-ka/* + person markers, Athpare *-ung* after finite markers.) The eastern IA languages (Assamese, Bengali, Oriya) moreover have a conditional converb, as do most Dravidian languages.

(4) ASSAMESE (IA) mɔi aahi-**le** 'if I come'
ORIYA (IA) se asi-**le** 'if he comes'
TAMIL (DR) maẓai peyt-**aal** 'if it rains'
KANNADA (DR) avaru oodid-**are** 'if he studies'

Santali has nonfinite forms in *-kate* and *-te* (5a); the quasi-converbs carry finite tense-aspect and person markers, though they lack the finite marker *-a* (5b).

(5) SANTALI (MU)

a. calak'-calak'-**te** mit'-ṭaŋ
go:MID-REDPL-CONV.SIM *one*-CLASS
toyo-ko ɲɛl-tiok'-ked-e-a
jackal-S:3PL *see-reach*-PT-O:3SG-FIN
'While they were walking, they got sight of a jackal'

b. kɔṭɛc'-ked-e-**khɔn** ḍaŋgra-dɔ-e
castrate-PT-O:3SG-ABL *bullock*-TOP-S:3SG
luṭkum-en-a
fat-PT:MID-FIN
'Since they castrated it, the bullock became fat'

The South Asian picture is far from uniform, and the number of converbs can vary from one to ten or more (e.g., Hayu), although three or four is the norm. Converbs are even more characteristic of Central and Northeast Asian languages, where converbal forms mark all types of adverbial subordination. Moreover, converbs seem to go together with OV word order (Ethiopian Semitic and Quechua). So do adnominal 'relative participles,' which are sometimes mentioned together with converbs as an areal trait of South Asia.

Compound Verbs

South Asian languages form compound verbs consisting of the general/sequential converb form of the main verb (V1) followed by a finite form of a second verb (V2). The second verb, which also occurs as a full verb, is semantically bleached, but not fully grammaticized. The inventory of second verbs listed in grammars differs somewhat from language to language, and – as the list is not closed – also from author to author. The most frequent V2s include:

1. directionals with the full verb meanings 'go', 'come';
2. disposals that express that something is done away with, such as 'throw', 'send', 'put aside';
3. verbs that express the suddenness or unexpectedness of an event, such as 'fall', 'rise';
4. 'give' and 'take' have auto- and other-benefactive meanings as V2.

(6) MARATHI (IA)
sagḷe kaagad mi phaaṛ-un ṭ**aak**-le
all paper I tear-CONV V2:THROW-PT
'I tore up all the papers'

BENGALI (IA)
se mar-e **ge**la
he die-CONV V2:GO:PT
'He died'

KANNADA (DR)
avaru sattu-**hoo**-daru
s/he die:CONV-V2:GO-PT:3PL(HON)
'He died'

The terminology used for this construction is rather inconsistent. Apart from a plethora of names for the V2 (explicator, vector, aspectivizer, light verb), some authors use the term *serial verb* instead of compound verb. Sometimes constructions with phasal verbs (which are not semantically bleached and often combine with the infinitive) and grammaticized forms are included.

As with converbs, a closer look at compound verbs yields a rather diverse picture. First, the shape often differs from the canonical 'V1-CONV + V2 finite' pattern. Some languages have developed new converb suffixes or an optional long form. The new or long forms are used in clause combining, but not in compound verbs. Thus Hindi and Panjabi never have the converbal suffixes *-kar* or *-ke* in compound verbs, but use an old form now reduced to the bare stem of V1 (see *par ga-yaa* in (1c)); Oriya never has *-iki* or *-ikɔri*; Koḍava never has the converb in *-iti*, but the old converb, which is identical with the past stem (see the Tamil and Kannada examples above).

(7) ORIYA (IA)
pila-mane pɔṛh-**iki** ghɔr-u
child-PL *study*-CONV *house*-ABL
bahar-**i-gɔl**-e
go.out-CONV-V2:GO:PT-3:PL
'After studying the children went out of the house'

KOḌAVA (DR)
ava seebɨ tind-**itɨ**
she apple eat:PT-CONV
cat**tɨ-pooc**-i
die:PT:CONV-V2:GO:PT-3
'She ate the apple and died'

Santali root compounds look much like the Hindi and Panjabi forms. Languages that make little use of converbs often have finite markers on both verbs, such as Kurukh and some MU and TB languages.

(8) SANTALI (MU) tɔl-**uric′**-ked-e-a-e
tie-V2:FIRM-PT-O:3SG-FIN-S:3SG
'he tied him up firmly'

KURUKH (DR) iirk-an-**cicc**k-an
see:PT-1SG-V2:GIVE:PT-1SG
'I looked after it'

PARENGI(MU) silay-ing-**ta'y**-ing
sew-1SG-V2:GIVE-1SG
'sew for me!'

CAMLING(TB) c-ung-**pak**-ung-a
eat-1SG-V2:PUT-1SG-PT
'I ate it up'

Second, the inventory and semantics of second verbs sometimes differ in substantial ways from more canonical patterns, especially in MU and N-DRAV. The unusual V2s include Santali *jaora* 'gather', *uric′* 'make firm', *ɛsɛt′* 'close', *nyam* 'find', *aŋga* 'dawn', and Kurukh *xacc-* 'break', *biʔ-* 'cook'. Tamil also has unusual second verbs, and even the common ones show irregular semantics, often conveying purely emotional meanings.

Compound verbs of the form "V1-CONV + V2 finite" are typical of Altaic (with V2 called postverb, descriptive verb, or auxiliary). Turkic and Mongolic languages share the second verbs mentioned under (a) to (d) above. But unlike South Asian languages they make regular use of postural verbs as atelicizers or durative markers. Otherwise the use of second verbs in languages in the northern part of India appears to be more similar to Turkic-Mongolian than to South Dravidian, though further detailed studies are needed.

Quotatives

Quotatives of the form 'say'-CONV, such as Bengali (IA) *bole*, Nepali (IA) *bhanera*, Telugu (DR) *ani*, Santali

(MU) *mente,* and Sora (MU) *gamle* correspond to Uzbek (TURKIC) *deb*, Mongolian *geǰ* (and to Ethiopic Inor *barə* Quechua *nishpa*). There is nothing remarkable about the development into complementizers, which are then used together with verbs characterizing speech or mental acts, or with onomatopoetic words. The development from 'say' to complementizer is also attested in African languages and Creoles. It is an ongoing process that can be observed in South Asia, and not all languages are at the same stage. The last stage, comparatives marked by the quotative, is attested only in some languages of Nepal (e.g., Newar, Nepali) and South Dravidian. Further detailed studies are necessary to describe the use of quotatives in the single languages and to distinguish borrowings from internal developments.

Morphological Causatives

All languages of South Asia show morphological causatives, and most have secondary or indirect forms.

(9)	HINDI (IA)	*siikh- / sikhaa- / sikhwaa-* 'learn /teach / have taught'
	KASHMIRI (IA)	*con- / caavun- / caavinaavun-* 'drink / give to drink / let give to drink'
	MALAYAL (DR)	*oṭi- / oṭikk- / oṭippik-* 'break (intr/tr) /let break'

The patterns differ toward the east, where prefixes prevail. AA languages thus conform to their relatives in Southeast Asia: Khasi *tip / pn-tip* 'know / inform', *iap / pn-iap* 'die / kill', and Sora *jum / a-jumjum* 'eat / feed'. TB languages of the east also have prefixes, e.g., Mao Naga *apo / so-pho* 'break (intr/tr)'; Mikir *thì* 'die', *pe-thì* 'kill', *pa-pe-thì* 'let kill'. In some languages, double causatives can receive a simple causative interpretation; Kharia (MU) *ḍoko* 'sit down', *ob-ḍo-b-ko-yoʔ* (CAUS-sit-CAUS-sit-PTII) 'he made him make her sit' or 'he made him sit' (Zide and Anderson, 2001: 521, 523).

Morphological causatives, including double causatives, are also found in the languages of Central and Northeast Asia.

Dative Subjects

This construction is familiar from some European languages such as Latin and German. An experiencer is coded by the dative (in Eastern IA languages by the genitive), and the dative constituent behaves like a subject in some respects (Verma and Mohanan, 1990).

(10)	HINDI (IA)	bacce-**ko**	ṭhaṇḍ	lag	rahii	hai.
		child-DAT	*cold*	*feel*	PROG:FEM:SG	*is*
		'The child is/feels cold'				
	TAMIL (DR)	ena-**kku**	kuḷiraa	iru-kk-utu.		
		he-DAT	*cold*	*be*-PRES-3SG:NEUT		
		'He is/feels cold'				

The construction is less prominent in MU and TB; some languages even lack a dative or an oblique case marker. Nevertheless, it counts as a strong areal feature; as in contrast to the constructions mentioned above, it does not exist in Altaic languages. As it is not typical of Sanskrit, DRAV is usually considered a likely source.

Other Features

Several other features were claimed to be characteristic of South Asia, but most were dropped later, e.g., aspirated consonants, nasalized vowels, classifiers, ergative constructions, no prefixes, no verb for 'have'. The proposed features were evaluated by Masica (1976: 187–190); most of them turned out to be irrelevant or of little relevance for the South Asian linguistic area. Classifiers and echo formations were suggested in Emeneau's pioneering article 'India as a linguistic area' (1956). Emeneau erroneusly considered classifiers, which occur especially in eastern and central India, as borrowings from IA into the individual MU and DRAV languages. But classifiers clearly have swept over from Southeast Asia. Emeneau's conclusion probably has to be ascribed to the fact that the classifiers of MU and N-DRAV languages often have an IA shape; i.e., the morphemes are borrowed, but the function is not.

Most South Asian languages have a construction in which a word is reduplicated, replacing the first consonant (sometimes also the following vowel), so that the second word constitutes an echo of the first one. The echo expresses 'and such things', e.g., Tamil *kudirai-gidirai* 'horses and such things'. The consonants used in echo formation are distributed in areal patterns (see map in Trivedi, 1990: 80–81). Dravidian languages of the south show exclusively *k, g;* Orissa and Bengal have *p, ph* or *ṭ*. The patterns are independent of genetic affiliation; compare Oriya (IA) *iskul-phiskul* 'school and such', *cini-phini* 'sugar and such' with Ho (MU), *ɔpis-pɔpis* 'office and such'; Bengali (IA) *ghusur-ṭusur* 'pigs and such' with Nocte (TB) *san-ṭan* 'sun and such', and Santali (MU) *bɔkɔp-ṭɔkɔp* 'brothers and such'. Emeneau considered this feature to be borrowed from DRAV, as he took it to be otherwise unknown in Indo-European. (It is rare in IE, though not in Altaic; Turkish *kitap mitap* 'books and such things', Uzbek *nån pån* 'bread and other baked goods').

A more promising candidate seemed to be the Sanskrit particle *api,* corresponding to Tamil *-um*, which has five functions reconstructable for Proto-Dravidian: 1. additive focus, 'also', 2. 'and', 3. 'even', 4. totality with numerals ('every'), 5. together with question words it yields indefinite pronouns. Emeneau found the five functions in all

subgroups of DRAV, but only in a few modern IA languages (e.g., Marathi, Oriya). As not all functions exist in early Vedic, he concluded that the functions of Sanskrit *api* developed by analogy with the DRAV model (Emeneau, 1980: 218). No parallels in MU or TB are mentioned. Nevertheless, it is one of the few features that Masica considers to be area-defining, though the criteria are not further discussed and remain unclear. The bundle of functions 1.5. is far from rare for a particle meaning 'also, even', and parallels could be cited from Altaic and many other languages.

History of the Field

South Asia counts as a classic example of a linguistic area. As early as the 19th century, Indologists noticed some common traits between IA and DRAV. The discussion centered around the question of whether IA could have adopted certain features from DRAV, e.g., retroflex consonants or converbs. Sanskritists have at all times tried to minimize such possible influence and proposed internal developments (Hock, 2001). Emeneau, doing intensive research on DRAV, was the first to put the comparison on a more solid base. In his early article 'India as a linguistic area,' he came to the conclusion that "the languages of the two families, Indo-Aryan and Dravidian, seem in many respects more akin to one another than Indo-Aryan does to other Indo-European languages" (1980: 119–120; 1956). His definition of the term *linguistic area* as "an area which includes languages belonging to more than one family but showing traits in common which are found not to belong to the other members of (at least) one of the families" is still useful, in contrast to his later proposals. In the introductory article to the reprint volume (Emeneau, 1980), he critically reviews his own earlier work and adds the conditions: For a feature to be area-defining it has to be "pan-Indic and not extra-Indic" (1980: 2). Only if several such features are found and the area is delimited by a bundle of near isoglosses can the linguistic area, in his view, be considered established. A second step has to show the origin of the areal features and their distribution. If a feature can be reconstructed for language X, it must have been borrowed into language Y.

The newly formulated conditions turn out to be problematic. If a South Asian areal trait must not be extra-Indic, most of the proposed features have to be abandoned. But this criterion does not seem to have been taken too seriously anyway; few researchers have bothered to look outside the borders of South Asia. This is true even of Emeneau himself, as evidenced by his proposals for classifiers and echo words as areal traits. And the criterion of pan-Indianness was not tested. Areal relevance was mostly claimed on the basis of a few examples from IA and DRAV, sometimes adding one or two examples from a MU language. Isogloss bundles were not shown, as Emeneau remarks: "Unfortunately I know of no demonstration of such a bundling of isoglosses" (1980: 128).

In an important article, Kuiper (1967) examined Vedic and Sanskrit texts that could shed light on the origin of the South Asian linguistic area. He investigated the appearance of retroflex consonants, converbs ('gerunds'), and the development of the quotative *íti* in IA. Regarding retroflexes, he comes to the conclusion that prehistoric bilingual speakers of IA – presumably native speakers of a Dravidian language – reinterpreted IA allophones in terms of their native system, thus establishing a novel phonemic distinction in IA. Kuiper further traces the gradual increase of converbs in the successive *Rigveda* texts and ascribes the development again to bilinguals, who would have used converbal constructions first in colloquial speech, from where it crept into more formal registers. The Sanskrit particle *íti* 'thus' originally introduced quotations and is attested in initial position in Vedic texts. Gradually it became post-quotative by analogy with the Dravidian 'say'-CONV, and in later Sanskrit this was the standard.

A further influential article was Southworth's contribution to the volume edited by himself and Apte (1974). Southworth found that the frequencies of retroflex consonants in modern IA languages decreases from west to east. Western IA languages such as Marathi, Gujarati, and Panjabi show a ratio of 3:1 for dentals and retroflexes, which corresponds to the ratio in DRAV, but Bengali has 12:1 (1974: 212). Southworth interprets this, together with gender marking, as evidence for a DRAV substratum in the west; the lower number of retroflexes and the presence of classifiers is interpreted as a reflex of a TB substratum in the Ganges delta and the east. The assumption that the distribution of features today mirrors the situation that obtained 2000 years ago is of course problematic.

The first comprehensive and systematic study on some features in South Asia and beyond, Masica's *Defining a linguistic area: South Asia* (1976), has become a standard text. Whereas earlier publications on the sprachbund were confined to demonstrating shared features of South Asian languages (if not just IA and DRAV), Masica's concern was to find out to what extent these features are purely South Asian. The results are rather devastating for the sprachbund hypothesis if based on the conditions formulated by Emeneau: of the five traits investigated, only one, namely dative subjects, turned out to be specific for South Asia. The other four

– morphological causatives, OV word order, converbs, and compound verbs – are equally characteristic of most languages of Central and Northeast Asia, as already mentioned. Researchers have since also spoken of an Indo-Turanian area.

The idea of a South Asian sprachbund is thereby not invalidated. The clustering of the two essential features, dative subject and retroflexes, together with shared idioms and semantics (Emeneau, 1980: 236, 250; Masica, 2001: 258) and the OV characteristics, some of which demonstrably spread from South Asian centers, together add up to the often perceived 'Indianness' of South Asian languages.

Historical Evidence

One of the aims of identifying linguistic areas is to find evidence for earlier settlements and migrations. Documentation of South Asian languages reaches back to the second millennium B.C. for Sanskrit and back two millennia for Tamil, but little is known about earlier stages of MU and TB. And in spite of the early attestations of IA and DRAV, the substratal influence of the latter on the former remains controversial. According to Hock (2001), IA and DRAV were typologically more similar at the time of the earliest contacts than is commonly assumed. Similarities such as the combination of finite marked forms, as still preferred in North and Central Dravidian, have been demonstrated by Steever (1993) for older stages of South Dravidian. Many of the South Asian traits could be retentions, being strengthened of course by area-specific preferences. Hock criticizes the still prevailing practice of drawing conclusions from comparisons of Sanskrit with (mainly) modern South Dravidian, ignoring older traits of Dravidian and setting aside 2000 years of history.

Even the DRAV origin of retroflexes, a seemingly solid cornerstone of the substratum hypothesis, has been questioned. This also casts doubt on the general assumption that Dravidians were the inhabitants of the Indus Valley at the time the Indo-Aryan infiltration into South Asia started. Witzel (1999) posits a 'Para-Munda' substratum of the oldest IA documents, i.e., the Vedic texts, which originate from the valley.

More recent influences can be traced by means of quantitative areal investigations. Hook (1987), trying to get "at the grain of history," reports an interesting finding from a questionnaire investigation. In the returns from south of Goa, all subordinate clauses were preposed; the percentage gradually decreased toward the northwest, i.e., with the distance from the Dravidian model. West of the Indus, all clauses were postposed. This pattern is independent of the fact that OV word order typologically often goes together with preposed clauses and demonstrates the fading out of a typical feature toward the edge.

A quantitative analysis of this type can sometimes show the areal spread of a trait, though not its origin. The inference from present-day frequencies to situations 2000–3000 years back (Southworth, 1974) is hardly reliable. Hook's endeavors to trace the possible origin of compound verbs on the basis of frequency counts lead to no satisfying results. Today compound verbs are most abundant in the Ganges plains (Hindi 15–20% of total verbs, modern Bangla 10–13%, modern Marwari 13–18%). But comparison with the situation in 16th century Bangla (2%) and Marwari (1.5%) shows this to be a recent phenomenon (Hook, 2001: 109). If borrowed at all, the further development of the construction must be ascribed to internal forces. Hook's answer to the question of what we can conclude from the present-day distribution of the compound verb in the languages of South Asia is: "Not much." (2001: 110). Various processes of borrowing, internal developments, and even of loss are possible scenarios.

Much of the linguistic history of South Asia remains in the dark. Shifts in language have not been uncommon, and in some cases have occurred more than once, e.g., from MU to DRAV to IA. Widespread bilingualism and multilingualism have repeatedly lead to pidginization and the development of lingua francas, such as Calcutta-Hindustani or Hindi-Urdu in Bombay. Nagamese, based on IA Assamese, has become the mother tongue of the Tibeto-Burman Kachari. It is at present the only common medium of speakers of the 30 or so Tibeto-Burman Naga languages. Sadari, a Hindi based pidgin, has become the language of identification for groups who have abandoned their former DRAV or MU tongues. Some of the modern literary languages may have started out as pidgins too, as Southworth (1971) suggests for Marathi.

Historical investigations are restricted to what has been accepted into the written language. But written texts are far from an ideal basis for areal investigations, and written norms are especially conservative in South Asia. At all times, the spoken language has differed a great deal from the written one, and borrowings must have been much more abundant than texts reveal. Present investigations into languages used for everyday communication show remarkable structural convergences in some areas. The most well-known case is Kupwar, as described by Gumperz and Wilson (1971). The contact situation between Kannada, Marathi, and Urdu at the border between Maharashtra and Karnataka has lead to one single grammatical system with language-specific lexemes. This study also reveals another characteristic of linguistic areas: structural traits, especially in syntax, are largely unconscious and easily borrowed, whereas there may be considerable resistance toward lexical

borrowing, especially if the language functions as a means of identification.

Subareas

Setting up isoglosses simply on the basis of the occurrence of a feature, as in Masica (1976), is apparently not an adequate technique for showing the intricate patterns of a linguistic area. In Masica's map of the dative subject, for example, the isogloss for this construction includes the northeastern corner of India. The map does not show that this feature is mainly restricted to IA and that numerous small languages of the area have not adopted it. As Masica himself notes (1976: 172), the isogloss maps do not show the gradual fading out of features. They also do not indicate different codings. If causatives are marked by suffixes in the west, but by prefixes in the east of the subcontinent, this is highly relevant for areal studies.

One of Masica's four Indo-Altaic isoglosses deviates from the others: The line for secondary causatives runs approximately along the 84th meridian, i.e., cutting off Bihar, parts of Orissa, and the northeastern provinces from the rest of South Asia. This line is indeed relevant, though not primarily for the feature intended by Masica. Double causatives do exist to the east of it. East of the 84th meridian, two areas can be set off: (A) a former contact zone between TB, AA, and DRAV, stretching from eastern Nepal to Orissa, and (B) the predominantly TB northeast. Only a few of the more than 100 languages of those tribal areas have been described, and hardly any of them has been considered in areal studies. The Non-IA languages from Nepal to Orissa (zone A) are characterized by a complex verbal morphology, which is not characteristic of the TB relatives farther north and east and may be due either to MU, which seems to have had a complex morphology at all times (Zide and Anderson, 2001), or to an unidentified third substratum (referred to, e.g., in Hook, 2001: 124; Witzel, 1999: 40). Different from the converbal structures typical of OV languages, much of the complex pattern of person and tense-aspect marking is retained in subordination in MU languages, in Kurukh, and in Kiranti languages of eastern Nepal. Sometimes only the finite or final marker is missing, as in Santali and Athpare. It seems that long contact between DRAV, MU, TB, and possibly other language groups have lead to an area little affected by the rest of South Asian language developments (Ebert, 1999: 392).

Subareas have been claimed for the Khondmals, for Jharkhand, for the Northwest Frontier, and others. This does not invalidate the hypothesis of a South Asian linguistic area, just as sharing the OV characteristics with Central Asia does not. We should not be surprised to find subareas within subareas without clear boundaries. "Sprachbund situations are notoriously messy," as Thomason and Kaufman (1988: 95) put it. But we should not look for "pan-Indic and not extra-Indic" features, as Emeneau suggested. Instead, research must concentrate on more detailed investigations of certain phenomena, such as compound verbs or converbs, which show uneven frequencies and idiosyncratic forms in subareas. The clustering of features in certain subareas is characteristic of linguistic areas, just as is their diffusion into a number of unrelated languages.

South Asia: Religions

R V Pandharipande, University of Illinois at Urbana-Champaign, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

South Asia is a multilingual and multireligious region. Currently, the major indigenous religions in the region are Hinduism, Sikhism, Jainism, Buddhism; Zorashtranism and Islam are imported religions. Additionally, there are many variants of these major religions and many diverse local belief systems, which show a mixture of beliefs of diverse systems. The dynamic historical, linguistic, and geographic landscapes have created a complex, mind-boggling, but fascinating panorama of languages of religions in South Asia.

Multilingualism in South Asia adds a complex and distinctive character to the relationship between languages and religions. One of the striking features of the language of religion in this region is that there is no fixed equation of one linguistic form for one religion. Many languages are used to express one religion and one language is used to express many religions. For example, Christianity is expressed through English (in India, Pakistan, Bangladesh, Sri Lanka, among others), Portuguese/Konkani (in Goa), Tamil (in Tamilnadu), Hindi (in India), Simhala (in Sri Lanka), Urdu (in Pakistan), and Bangla (Bengali) (in Bangladesh), etc. Similarly, Hindi is used to express not only Hinduism, but also Buddhism, Christianity, and Jainism. Moreover, within the same religious community, different languages are used to perform different religious functions, thereby creating a diglossic situation. Additionally, there are various registers of regional religious languages such as Arabicized, Persianized, and Sanskritized varieties of Hindi, Marathi, Sindhi, etc.

Any discussion on the language of religion in South Asia must take into account the above-mentioned complexities of the relationship between language and religion in the region in order to understand the variation within each of the systems of religion related to the (a) the definition of language of religion, (b) the linguistic strategies to express religious content, (c) the notion of efficacy of religious code, (d) language of the scriptures, (e) sacred scripts, and (f) authority and authentication of religious language.

The following questions need to be raised in the context of South Asia:

1. Why is there variation in the language of religion? Why are there several languages used for one religion?
2. Is the choice of languages random? What are the determinants of language choice?
3. How do languages of religions vary across time?
4. When a new religious code is introduced to carry out the function of the earlier code (which functioned as the religious code), what happens to the earlier code? Why do they coexist?
5. Which authority implements and authenticates the change?
6. Does the authority remain constant across time?
7. When one religious code is replaced by another, do the structure of the linguistic code and religious content undergo change?

Introduction

South Asia is a multilingual and multireligious region. Currently, the major indigenous religions in the region are Hinduism, Sikhism, Jainism, Buddhism; Zorashtranism and Islam are imported religions. Additionally, there are many variants of these major religions and many diverse local belief systems, which show a mixture of beliefs of diverse systems. The dynamic historical, linguistic, and geographic landscapes have created a complex, mind-boggling, but fascinating panorama of languages of religions in South Asia.

Multilingualism in South Asia adds a complex and distinctive character to the relationship between languages and religions. One of the striking features of the language of religion in this region is that there is no fixed equation of one linguistic form for one religion. Many languages are used to express one religion and one language is used to express many religions. For example, Christianity is expressed through English (in India, Pakistan, Bangladesh, Sri Lanka, among others), Portuguese/Konkani (in Goa), Tamil (in Tamilnadu), Hindi (in India), Simhala (in Sri Lanka), Urdu (in Pakistan), and Bangla (Bengali) (in Bangladesh), etc. Similarly, Hindi is used to express not only Hinduism, but also Buddhism, Christianity, and Jainism. Moreover, within the same religious community, different languages are used to perform different religious functions, thereby creating a diglossic situation. Additionally, there are various registers of regional religious languages such as Arabicized, Persianized, and Sanskritized varieties of Hindi, Marathi, Sindhi, etc.

Any discussion on the language of religion in South Asia must take into account the above-mentioned complexities of the relationship between language and religion in the region in order to understand the variation within each of the systems of religion related to the (a) the definition of language of religion, (b) the linguistic strategies to express religious content, (c) the notion of efficacy of religious code, (d) language of the scriptures, (e) sacred scripts, and (f) authority and authentication of religious language.

The following questions need to be raised in the context of South Asia:

1. Why is there variation in the language of religion? Why are there several languages used for one religion?
2. Is the choice of languages random? What are the determinants of language choice?
3. How do languages of religions vary across time?
4. When a new religious code is introduced to carry out the function of the earlier code (which functioned as the religious code), what happens to the earlier code? Why do they coexist?
5. Which authority implements and authenticates the change?
6. Does the authority remain constant across time?
7. When one religious code is replaced by another, do the structure of the linguistic code and religious content undergo change?

These questions will be discussed in the context of the dynamics of the diachronic and synchronic sociocultural history, religious beliefs, language ideologies, and authority. The discussion is divided into ten sections:

1. A profile of languages of religions in South Asia.
2. Historical developments of languages of religion.
3. Ideology and power hierarchy: the ancient and the medieval period.
4. Ideology, power hierarchy, and language choice in contemporary South Asia.
5. Modernization, composite identities, and ideology of language mixing.
   The question of functional transparency.
6. The impact of multiple linkage on the structure of the languages: linguistic convergence.
   Genres of religious discourse.
7. Authority.
8. Script as a determinant of religious language.
9. Contributions of the religious language to linguistics.
10. Conclusion.

Before we proceed to discuss the languages of religions in South Asia, it is necessary to briefly describe the constituents of language of religion. There are three basic components of language of religion: its form or linguistic structure, its religious content, and its function (see Figure 1).

The combination of these three varies across religions. Even within the same religion, it changes across time. It will be shown that the patterns of variation in the choice of codes across time and space can be explained in a straightforward fashion within the framework of the ideology and hierarchy of language power.

The following discussion demonstrates that in South Asia, different languages are perceived as powerful in different domains. Even within the same domain of religion, not all languages are perceived as equally powerful. At any given point in time, there is a hierarchy of power of linguistic codes to express a particular religion. The choice of the code for expressing a particular religion is determined by the code's degree of power. The power of a code to express a religion as well as the hierarchy are determined by the ideology of the religious communities. The ideology is implemented by the 'authority,' which serves as the medium or mechanism through which the choice of the codes for particular religions is institutionalized.

The ideology and the authority change across time and space; consequently, the power hierarchy of the codes is restructured. It will be shown that the use of one code for many religions and the use of many codes expressing one religion have an impact on the structure of the codes as well as on the religious content.

Figure 1 Language of religion.

A Profile of the Languages of Religions in South Asia

The population in South Asia is diverse and the degree of concentration of different religions varies across different regions. India's population can be broken down into the following religious groups: Hindus approximately 83%, Muslims roughly 11%, Christians approximately 3%, Sikhs about 2%, Buddhists roughly 0.75%, and Jains less than 0.5%. Other religions constitute less than 0.5% of the population. In contrast, Pakistan and Bangladesh have a relatively larger concentration of Muslims and a significantly smaller percentage of the Hindu and other religious communities. Sri Lanka has a larger Buddhist community compared to India and Pakistan. Similarly, the distribution of languages varies significantly across South Asia. While a major concentration of Indo-Aryan languages is observed in North India, Pakistan, Bangladesh, Nepal, and Sri Lanka, the Dravidian languages are primarily concentrated in South India and Sri Lanka. Tibeto-Burman languages are dominant in the northeastern regions in South Asia (India, Nepal, Tibet, and Bangladesh).

Distribution of Languages Across Religions

The current distribution of languages across religions is given in the following figures.

Figure 2 shows that English, as well as other languages that were not used earlier, are now used to express Hinduism. Within these languages, two varieties are observed, one that shows a marked influence of Sanskrit and the other that does not (e.g., Dravidian, and other NSA [New South Asian] languages). It

Figure 2 Hinduism.

is also important to note that the languages that are typically not used for Hinduism are Arabic, Persian, Portuguese, Pali, and Arabicized and Persianized varieties of modern South Asian languages. However, here a distinction is made between a language and its writing systems, for example, the Persian script was used for the Sanskrit religious texts in Kashmir by the *pandits* (see Pushp and Warikoo, 1996).

As shown in Figure 3, the languages of Islam are Arabic, Persian, Urdu, and Arabicized or Persianized NSA languages. The languages that are typically not used for Islam are Sanskrit, English, Portuguese, Pali, and Sanskritized or 'Englishized' varieties of modern South Asian languages.

Pali and NSA languages are used for Buddhism. Sanskrit, Arabic, Persian, and Sanskritized, Arabicized, or Persianized varieties NSA languages are not used (Figure 4).

While Portuguese, Latin, Syriac, English, and NSA languages are used for Christianity, the use of Sanskrit, Arabic, Persian, and Pali is strictly prohibited (Figure 5).

While the language of the Sikh scripture (Guru Granth Sahab) is a combination of Old Panjabi (Lahanda) and Khadi Boli, modern Panjabi is readily used for religious discourses in current South Asia (Figure 6).

The language of old Jain scriptures is Ardhamāgadhī (Middle Indo-Aryan). However, its use is largely replaced by the NSA languages. A large literature is written in Kannada and Hindi (as well as other NSA languages) (Figure 7).

The choice of a language for a religion is not random. Although more than one language is used for Hinduism, Islam, Buddhism, and Christianity, some languages are typically excluded from the list of options. Furthermore, it needs to be noted here that the pattern of languages shown in the above figures has not been constant through the history of these religions. For example, the use of NSA languages for these religions is relatively recent (for the most part after 1200 C.E.). Also, the use of Sanskrit and Arabic, the classical languages of Hinduism and Islam, respectively, which was more restricted in the medieval period, is on the rise in contemporary South Asia. The use of English for Hinduism has a history of almost 200 years. The use of English for the religious discourse of Hinduism was enhanced by the English discourses of Vivekānanda (19th century), as well as by the mystic saints such as Aurobindo (20th century). Moreover, the English translations of the Vedas (Max Muller in particular) propagated understanding of the Hindu texts in the west. The term 'Hinduism' (the Persian word Hindu with the English suffix) was legitimized during the 19th century. A large number of exchanges of concepts and lexicon between Sanskrit and English took place during this time. However, the use of English was largely restricted to the philosophical and religious discourse, and the use of Sanskrit and regional languages in the ritual performances of Hinduism was common.

Historical Development of Languages of Religions in South Asia

The following discussion outlines the major historical developments that contributed to the emergence of many languages for each of the religions.

The medieval period (after 1200 C.E.) marked a major shift in the pattern of languages used to express religions. Before this period, the status 'language of religion' was enjoyed for the most part by one language for one religion. For example, the classical languages such as Sanskrit (for Hinduism), Arabic/Persian (for Islam), Pali/Hybrid Sanskrit (for Buddhism), and Ardhamagadhi (for Jainism), and Latin (for Christianity) were considered to be the linguistic codes endowed with the 'power' or efficacy to express their corresponding religions. Other South Asian languages were excluded from the domain of religion. During the period 1200–1700 C.E., mystics and saints from various parts of India such as Bāsavaṇṇā (12th century C.E.) in Karanataka, Jnāneśwar (13th century C.E.) in Maharashtra, the Aḷvars and Nammāḷvār in Tamilnadu (14th and 15th centuries C.E.), Mīrābāī, and Tulsīdās in the north (15th century C.E.), Nānak and Kabīr (16th century C.E.) among others, independently argued for the legitimacy of nonclassical and vernacular languages. They composed their religious poetry in vernacular regional languages such as Marathi, Tamil, Rajasthani, Awadhi, and Khadi Boli/Old Hindi. The mystics and saints were the integrators (see e.g., Ramanujan, 1973; Ranade, 1933) who, on the one hand, liberated the religions from the constraint of the linguistic form of their expression, and elevated the status of the vernacular languages on the other. For further discussion on the medieval Bhakti movements, see Dwivedi (1964),

Figure 3 Islam.

Figure 4 Buddhism.

Figure 5 Christianity.

Figure 6 Sikhism.

Nagendra (1973), Shukla (1929), and Varma (1947). The classical languages had become virtually inaccessible to the common people by this period. The use of NSA languages for religions brought the scriptures to the common people in their own languages.

The other major historical development during the medieval period was the translation of the scriptures (which were in the classical languages) into New South Asian vernacular languages. The impetus for translation came from the following:

1. The common people needed access to the scriptures and religions.
2. The Syrian, Roman Catholic, and the Protestant missionary activities in South Asia included conversion of the South Asian population to Christianity of these denominations. To facilitate this, it became necessary to translate the bible into local South Asian languages. The first Bible translation in the local (Konkani) language was *Doutrina Crista* (1622 C.E.) by the English Jesuit priest named Thomas Stephens. Large-scale conversions to Christianity continued throughout the British rule after the 18th century (see Hooper, 1963), which resulted in translations of the Bible into NSA languages. Thus, the use of languages other than the earlier languages of religion became prominent after the medieval period.
3. Buddhist texts, which were translated into Tibetan in the 7th century C.E., began to be used as the Buddhist canonical texts in the medieval period.
4. Although Arabic continued to occupy the central place in the orthodox mosque, several versified bilingual glossaries (Arabic to local languages) termed *Khaliq bari* or Sufi poetic romances and hymns were composed in modern South Asian Languages (Schimmel, 1973). The Qur'an was first translated into Persian in 1737 and later into several Urdu versions that inspired translations of the Qur'an in numerous South Asian languages (Tamil, 1873; Gujarati, 1879; Telugu, 1938; Kannada, 1949). It is important to note that the language of Buddhism in Sri Lanka and India remained the same, i.e., Pali and Hybrid Sanskrit (a Sanskritized variety of Middle Indo-Aryan), while the language of Sikhism, a mixture of Old Panjabi and Lahanda, was supplemented by modern Panjabi. Translations of Jain scriptures into Kannada and Hindi (in addition to other NSA languages) allowed use of many languages for the religion.

These historical events provide a background for understanding the use of the NSA languages for their corresponding religions. However, in order to better understand (a) the rationale for the coexistence of the earlier classical languages and the new South Asian languages as the religious codes, (b) why Hinduism, Buddhism, Christianity, and Jainism allowed the use of more than one language for its expression while Islam did not, and (c) why classical languages as well as the NSA languages are used in both the secular and religious domains, it is essential to go beyond the historical facts. In the following discussion, I will show the importance of ideology in answering these questions.

Ideology and Power Hierarchy: The Ancient and the Medieval Period

The discussion in this section will demonstrate that the variation and change in the pattern of the choice of languages for expressing religions is determined by the ideologies about the language of religion at different points in time in different religious systems. The change in ideology modifies the power hierarchy and consequently the choice of the language.

Current research on language ideology and power (Bourdieu, 1991; Fairclough, 1989; Fowler *et al.*, 1997; Hodge and Kress, 1988, among others) have shown beyond doubt that ideology, which is a system of beliefs, practices, and representations in the interest of an identifiable class in the society, creates linguistic power hierarchies. In the context of language of religion, I define ideology as the system of beliefs about the (a) linguistic form, (b) religious content, and (c) the function of language of religion at a given point in time within a community. In other words, it is the system of beliefs about the interrelationship among the three components (i.e., its form, content, and function/use) of the religious language.

Figure 7 Jainism.

The ideology provides a rationale for the choice of a particular language for expressing a particular religion. This framework ideology does not treat ideology exclusively as 'a distortion in perception of social and economic relations' (Luke, 1998: 366). The variability in each of these components of language of religion is explicable on the basis of the underlying ideology. This framework (a) allows the coexistence of many ideologies of diverse groups within the society, (b) provides a mechanism to identify diachronic changes in the ideology and thereby in language choice, and (c) explains variation in the language choice across religions.

The following discussion will address the issue of language choice in three major periods: ancient (pre-medieval), medieval, and contemporary. The historical evolution of language of religion (with its variability) discussed earlier, as well as its current situation, is explicable within the framework of language ideology and power.

First, let us look at the power hierarchy of religious languages in the ancient period (2000 B.C.E. through the medieval period) in South Asia. As mentioned earlier, Sanskrit was considered to be the only legitimate language of Hinduism. No other languages (Indo-Aryan or Dravidian) were viewed as appropriate to express Hinduism. In other words, Sanskrit was perceived as powerful while other languages were viewed as powerless. The ideology, which sanctioned this power hierarchy, viewed the language of religion as the divine code (*devavāṇī*,), which alone was endowed with the power or efficacy of expressing the ultimate truth (*satya*). The Vedas, the ancient Sanskrit texts, were viewed as the first 'revelations' of the early sages (*ṛṣis*) that were orally transmitted to the following generations as the truths about the phenomenal reality and its foundation in the higher reality, which lies beyond human conceptualization and thought. The term 'mantra,' literally 'that which protects when meditated upon,' had multiple meanings such as, 'the sacred formula (the Vedic hymns addressed to the deities),' 'verses recited at the Vedic rituals,' etc. The Vedic theologies of sound attributed the origin of the universe to the phonic sound and claimed that the language of the Vedas had the power of creation. When uttered flawlessly, it was assumed, the *mantras* had the power to bring about the intended results for the sacrificer (the performer of the Vedic ritual) (for further discussion on *mantra*, see Staal, 1989). The purity of the language was assumed to be the prerequisite for the success of the ritual. Thus the religious language was defined on the basis of both its linguistic structure and its content. This ideology sanctioned Sanskrit as the language of Hinduism to the exclusion of other languages. Similarly, a few centuries later (but before the medieval period), Islam treated Arabic alone as the language of religion. The Qur'an was believed to be the literal word of God revealed through the Prophet Muhammad. Pali and Hybrid Sanskrit remained the languages of Buddhism, and Ardhamāgadhī was considered to be the language of Jainism. Christianity was expressed exclusively through Syriac (in Kerala) and Latin (in the Roman Catholic churches in the south, mostly the western coast of India). In general, the language of the scriptures was viewed as the only appropriate form for expressing the corresponding religion. Similarly, the scriptures were the only source of the legitimate religious beliefs, and the function of the religious language was to express, promote, and follow the religious beliefs presented in the scriptures. There was no variation allowed in the form, content, and the religious function of the language. This ideology gave enormous power to the classical languages, while the regional languages were left totally powerless. Thus, it may be argued that it was the ideology that determined the choice of the classical (as opposed to the regional) languages for expressing religions in the ancient period.

The medieval period marked a major change in the ideology as well as the power hierarchy of religious languages. During this period, the ideology of what constituted language of religion changed significantly. Primacy of the religious content over the linguistic form (structure) was well accepted by the mystics and saints (as well as the religious communities). It was the religious content that was considered to be the differentia of the religious language and all languages, including Sanskrit and NSA languages, which were viewed as equally powerful and appropriate to express religious content. The plea of Jnāneśwar (13th century C.E.), who argued for the equality of all linguistic codes, was for legitimizing the NSA languages as legitimate languages of Hinduism (for further discussion, see Ranade, 1933). Jnāneśwar, who used Marathi, as opposed to Sanskrit for his commentary on the Bhagavadgītā, strongly argued that Marathi, a regional language, would win over the people with its power as it is clear from the following quote from Jnāneśwarī 6.14:

> madzā maraṭhātSi bolu kautuke, parī amṛtātehī paidzā djinke, aisī akṣare rasike, meḷawīna.

Figure 8 Power hierarchy: medieval period.

Figure 9 Power of hierarchy, expression of regional identity.

> 'My speech is Marathi indeed, but my composition for the connoisseurs will be so effective that it will surpass even ambrosia.'

This ideology can be called the sacralization of the secular codes. In other words, this ideology granted power to nonclassical regional Indian languages and sanctioned their use for expressing Hinduism. Moreover, this ideology also legitimized the use of more than one language (regional languages) for expressing Hinduism. The process of sacralization of new South Asian languages was expressed through two major trends, one that marked Sanskritization of New South Asian languages, thereby approximating them to Sanskrit by borrowing linguistic features of Sanskrit, and the second, their de-Sanskritization. Although both trends emphasized the legitimatization of the NSA languages in the religious domain, their assumptions and impact significantly differed from each other. The first trend of Sanskritization implicitly assumed superiority of Sanskrit over NSA codes and resulted in the development of a commonly shared Sanskritized register of NSA languages, thereby causing their convergence. In contrast, the intentional de-Sanskritization of the NSA languages asserted the legitimacy of NSA codes as well as the regional religious identity of the users as well as of Hinduism. The two power hierarchies given in Figure 8 and Figure 9 articulate the different linguistic realizations of the same ideology of the sacralization of the secular NSA codes.

Note that in Figure 9, it is shown that when the regional identity of the religion and of the users of the code was to be accentuated, Sanskrit was powerless since it did not express any regional variety of Hinduism; rather, it expressed the pan-South-Asian Hinduism (for further discussion, see Pandharipande, 2001).

The question regarding the simultaneous maintenance of Sanskrit and NSA languages as religious codes was solved by the religious community being diglossic. While Sanskrit was used in pan-South-Asian rituals (sacrifices, weddings, funerals, etc.), regional languages were used in household rituals and personal or regional rituals or worship ceremonies.

In the case of Christianity, the Bible translations allowed the use of NSA languages for Christianity. While Latin and Syriac continued to be used as the languages of Roman Catholic and Syrian Christianity, the use of Portuguese, English, and NSA languages became prevalent in Catholic and Protestant churches. Diglossia was introduced whereby Latin, Syriac, Portuguese, and English were used by the elite and the NSA languages were used by the new converts of the lower classes (for further discussion on Christianity in South Asia, See Brown, 1982; Shackle, 2001). The ideology was similar to that for Hinduism. It was the religious content that gave the identity as religious language to a code. The linguistic structure by itself was not viewed as endowed with particular efficacy.

In contrast to the above, Islam did not recognize NSA languages as legitimate codes for Islam. Arabic continued to occupy the central position as the language of Islam even though the local NSA languages had developed their Arabicized varieties. While those varieties marked the religious identity of the Muslim community, they were excluded from the rituals in the mosque. The ideology that justified this exclusion of the NSA languages from the traditional rituals was based on the understanding that the Qur'an is God's word transmitted to humans through the Prophet Muhammad. Therefore, the correct language of Islam had to be Arabic. Thus diglossia of Arabic and NSA languages marked the language of Islam as well.

In the case of Buddhism, NSA languages (including Tibetan in Tibet) (*see* **Buddhism, Tibetan**) were accepted as the religious codes, though Pali and Hybrid Sanskrit remained major languages of the Buddhist canon (for further discussion on Tibetan Buddhism, see Williams, 2001).

This shows that the ideologies were varied across religious systems, which gave rise to diverse power hierarchies and allowed use of many languages for one religion. It also pointed out that the ideologies were responsible for the emergence of diglossia as a strategy of maintenance of more than one code in the same religious domain. An interesting point to note

Figure 10 Heteroglossia of identities.

here is that the NSA languages were used for Hinduism, Christianity, Islam, and Buddhism. However, the use of the classical languages such as Sanskrit, Arabic, Latin, and languages such as Persian, Portuguese, and to a large extent English was restricted to their corresponding religions. No crossover of these languages to other religions is observed in medieval and contemporary South Asia.

Ideology, Power Hierarchy, and Language Choice in Contemporary South Asia

Although the patterns of language choice in the medieval and the contemporary periods in South Asia may seem similar, they are not the same. The most striking difference between the two patterns is that the domain-related diglossia that existed in the medieval period seems to be breaking down in contemporary South Asia. The languages are crossing over their earlier domains. In fact, at least two apparently contradictory processes seem to be currently operating in South Asia. For example, NSA languages are more readily used in the domain where earlier exclusively classical languages (Sanskrit for Hinduism, Arabic for Islam, Latin/Syriac for Christianity, Pali for Buddhism, etc.) were used in the more orthodox religious context such as weddings, funerals, naming ceremonies, etc. Moreover, religious sermons are readily delivered in the NSA languages mixed with the classical languages. This process, as mentioned earlier, can be called sacralization of the NSA languages. In contrast, the classical languages such as Sanskrit and Arabic are being revived in the secular context in contemporary South Asia. The English language, which was earlier excluded from the domain of Hinduism, is readily acceptable within the community for philosophical discussions, sermons, and theological discourses. Mixing NSA languages with English is seen as a strategy to popularize religious beliefs (of Christianity, Hinduism, Neo-Buddhism, and Islam) among the masses of diverse groups using mutually unintelligible languages.

These developments can be explained on the basis of the ideology regarding religious language. Within contemporary South Asia, the choice of a language for a particular religion is not determined by the social domain, but rather by its function, i.e., the socioreligious identity that it symbolizes. In contemporary South Asia, religion is one of the major symbols of social identity. South Asian society is largely divided on the basis of religion. Thus, Hinduism, Islam, Christianity, Sikhism, etc. mark not only the religious groups, but also the social groups. Embedded within the same religious/social group there are other identities such as the pan-South Asian religious/social group, regional religious/social groups, etc. Additionally, the regional groups are further divided along ethnic lines such as Aryan, Dravidian, etc. Each language expresses a particular type of religious/social group identity. The choice of a language is determined by the intended identity and power of the language to express it.

The correspondence here is not necessarily between the social domain and the linguistic code; rather, it is between the code and the identity. I would call this heteroglossia of identities. The connection between the codes and the identities is showed in Figure 10.

The classical languages Sanskrit, Arabic, and Pali symbolize the larger pan-South-Asian or Hindu, Muslim, and Christian and Buddhist universal identities (religious as well as social), respectively.

In contrast, NSA languages express the regional religious/social identities. For example, the use of Hindi for Christianity, or Bangla for Islam, and Tamil for Hinduism as religious codes express the regional version of their corresponding religions. Therefore, when the pan-Hindu identity is to be expressed, the most powerful code is the classical language.

The regional NSA languages are powerless in this context. On the other hand, if the regional identity is to be expressed, the power hierarchy is reversed. Regional languages, and not the classical languages, are powerful. It should be noted here that the use of English for Christianity is similar to the classical languages. However, the use of Syriac and Latin is also marginally maintained in some churches in Kerala. This is what I call the heteroglossia of identities.

The heteroglossia of identities include micro-level identities in many cases. It is interesting to note here that the regional languages (similar to the medieval period) use one of the two registers, one that shows the influence of the corresponding classical language and the other without it. For example, the use of Sanskritized Hindi or non-Sankritized Hindi can be readily used to express regional religious/social identity. Additionally, various dialects of Hindi are also used to express Hinduism. The choice of a language in this case is determined by the religious theme. In the northeastern part of India, Sanskrit is used for the Vedic rituals and chants, while in non-Vedic regional rituals NSA languages are used. The language of recitation and chanting is determined by the theme of worship of a particular deity. For example, for the worship of the Rāma, the language is generally Awadhī while for the worship of Kṛṣṇa, the language is generally Braj (the northwestern variety of Old Hindi). This choice is based on the languages of the sacred texts for the respective deities. While Rāmcharitmānas, a sacred text for Rāma is in Awadhī (northeastern variety of old Hindi), the texts for Kṛṣṇa are in Braj (for the discussion on thematic diglossia, see Pandharipande, 1992). However, in South India, the use of the regional languages, devoid of any Sanskrit influence, indicates intentional dissociation from the Indo-Aryan Hindu tradition and assertion of the Dravidian identity (for further discussion, see Hart, 1976; Narayanan, 1994; Zvelebil, 1974; **Zvelebil, Kamil V. (b. 1927)**).

The use of English (as opposed to Latin, Syriac, and Portuguese) for pan-South-Asian Christianity is becoming more common as the knowledge of the traditional languages for Christianity is rapidly decreasing.

Modernization, Composite Identities, and Ideology of Language Mixing

The ideology of heteroglossia is a consequence of modernization, a phenomenon that is characterized as the process of globalization as well as localization at the same time (Appadurai, 1996; Hall, 1996). While globalization (marked by technologization, Englishization, and homogenization) results in undermining, and, at times, obliterating differences within and across societies, it also causes emergence of local identities expressed by age-old symbols. While Sanskrit, Arabic, and Pali express the pan-South-Asian or universal Hindu, Muslim, and Buddhist identities, respectively, they diffuse those regional and ethnic differences that are embedded within the broad labels of Hinduism, Islam, and Buddhism. This increased awareness of the particular or local identities is symbolized and expressed by the use of regional languages.

The phenomenon that has not received attention in current research is mixing languages within the same event. For example, in a typical wedding ritual (in Maharashtra state in India), the priest conducts the ritual in Sanskrit while the concluding ritual of blessing the newly wedded couple (*mangalāṣṭaka* 'the eight auspicious verses') is in Marathi, while the content of the wedding invitation card can be in English. Another typical example of mixing of languages is the popular religious sermons delivered to the public on television or in the open air theater. The local language (for example, Hindi, Marathi, or Gujarati) is the primary language of the sermon. However, the use of Sanskrit quotations from the Hindu scriptures are abundant. English vocabulary is also mixed with the primary language of communication.

The reason for this mixing is that identities in South Asia (universal and local) do not exist mutually exclusively; rather, they exist simultaneously. The South Asian multilingual community consists of multiple identities, each performing an individual function. Each language symbolizes one identity. The use of Sanskrit in the above two events of Hinduism indicates the pan-South-Asian or universal Hindu identity of the group, the use of Marathi articulates the regional identity, and the use of English allows communication with the larger group with many mutually unintelligible languages. The use of English vocabulary in the public (popular) religious sermon is a strategy to express religion in common people's language, which contains a large body of English vocabulary.

Another interesting case of mixing languages is where Sanskrit, the classical language of Hinduism, is mixed with other NSA languages in the most secular context. For example, the logo of the insurance company owned by the government of India (Bharatīya Vimā Company) is in Sanskrit. It is a direct quote from one of the most prominent scriptures of Hindus (the *Bhagavadgītā* 9:22), *yogakṣemaṁ wahāmyaham,* 'I take care of their needs / I provide them security (who depend on me).' In the original text of the *Bhagavadgītā*, God Krishna advises Arjuna, his

Figure 11 Religious and language identities.

Figure 12 Functional transparency of regional and classical languages.

friend and devotee, to depend on him because God always takes care of those who depend on him. This quote is the appeal to the people to have faith in the insurance company. In the advertisement of this insurance company, this quote occurs in Sanskrit while the rest of the text in various NSA languages.

Another example of the Sanskrit quote is from a Hindu scripture, *Bṛhadlraṇyakopaniṣad* (1.3:28) *tamaso mā jyotirgamaya*, 'Lead me from the darkness to the light.' In the original scripture, this is a prayer to God to remove ignorance and bestow knowledge on the person offering the prayer. However, this quote is used as the caption in an advertisement of fabric for men's suits. The intended meaning is, 'Let the knowledge be dawned that this fabric is indeed the best. Let the ignorance about the quality of the fabric be alleviated.' This phenomenon of using religious language for promoting commercial products (the most secular purpose) is fairly common in South Asia. The linguistic form (Sanskrit) and the literal meaning of the religious language both serve the secular purpose. This process can be called the secularization of the religious language.

The ideology that justifies these three cases is based on the following two assumptions about the religious language: (a) religious language symbolizes religious as well as secular/social identity and (b) the identity of the NSA community at large is a composite one that allows use of multiple languages to express those identities.

While the innermost circle (1) in Figure 11 expresses the local/regional religious/social identity, the circle (2) expresses the broader, pan-South-Asian religious/social identity. The outer circle (3) expresses the composite identity of the religious community, which embeds the other two identities.

The Question of Functional Transparency

While NSA languages are readily used for different religions, the classical languages (Sanskrit, Arabic, Persian, and Pali) are restricted to their corresponding religions. For example, Sanskrit is not used for Islam or Christianity and Arabic is not used for Hinduism or Christianity. The reason is that these languages are perceived as functionally transparent, i.e., they are the languages of the ancient scriptures of their corresponding religions and they have always been unique markers of their corresponding religions. Therefore, their affinity with the respective religions was viewed as almost exclusive. In contrast, the NSA languages have not been functionally transparent. They came on the scene much later and their affinity with a particular religion was relatively less transparent (i.e., they each were used for more than one religion). Therefore, in the medieval period, they were chosen for Bible translations as well as for the translations of the Qur'an. This is the reason why in contemporary South Asia, the classical languages are used to symbolize the pan-South-Asian identity of their corresponding religions and religious/social communities. NSA languages are not used in this context since they cannot uniquely mark one religion or religious identity because they are used to express many religions (i.e., they are not functionally transparent). In contrast, regional languages, and not the classical languages, are functionally transparent with respect to the regional identities. Therefore, NSA languages are used to symbolize regional religious/social identities. The language with a higher degree of functional transparency has more power to carry out that function than the language with lower functional transparency. Moreover, the language with higher functional transparency (*vis-à-vis* a particular religion) is less likely to cross over to other religions (see Figure 12).

The Impact of Multiple Linkage on the Structure of the Languages: Convergence

The history of South Asia shows that different linguistic codes have been used for different religions. It has been demonstrated (Pandahripande, 1992, 2001) that languages undergo change when they are used for different religions, i.e., they develop different registers.

Figure 13 Different interpretations for *Iśvar* 'god' in different religious systems.
